DANKSAGUNG

Zuerst möchte ich ganz herzlich meinem Doktorvater Heribert Vollmer für die Betreuung, Hilfestellung und gemeinsame Forschung während meiner Promotionszeit danken – und dafür, dass er zu der besten Sorte Chef gehört, die ich mir vorstellen kann.

Weiter danke ich meinem Kollegen, Koautor und Büronachbarn Johannes Ebbing für zahlreiche gewinnbringende Diskussionen und gemeinsame Forschungsergebnisse. Des Weiteren möchte ich mich bei meinen weiteren Koautoren für die gemeinsame Forschung bedanken. Auch danke ich Juha Kontinen und Lauri Hella für meine erfolgreichen Besuche in Helsinki und Tampere. Ganz besonders bedanke ich mich bei meinem Kollegen Arne Meier für viele detaillierte Anregungen zur Verbesserung dieser Arbeit.

Außerdem danke ich meinen Eltern, dass sie mich immer in meinen Fähigkeiten bestärkt haben. Und am meisten danke ich meiner Frau Anna für ihre Unterstützung und unendliche Geduld auch während schwieriger Phasen.

ACKNOWLEDGEMENTS

First I want to thank my advisor Heribert Vollmer for his supervision, support and joint research during my time as a PhD student – and for being the best kind of boss I can imagine.

Further I thank my colleague, co-author and office neighbour Johannes Ebbing for numerous fruitful discussions and joint results. In addition, I want to thank my other co-authors for our joint research. Also, I thank Juha Kontinen and Lauri Hella for my successful visits to Helsinki and Tampere. Especially, I thank my colleague Arne Meier for many detailed suggestions for improving this thesis.

Furthermore I thank my parents for always having encouraged me in my abilities. And above all I thank my wife Anna for her support and unlimited patience even during difficult phases.

ZUSAMMENFASSUNG

In dieser Arbeit wird (modale) Dependence-Logik untersucht. Diese wurde 2007 von Jouko Väänänen eingeführt und ist eine Erweiterung der Logik erster Stufe (bzw. der Modallogik) um den Dependence-Operator $=\!(\cdot)$. Für Variablen erster Stufe (bzw. propositionale Variablen) $x_1, \ldots, x_n$ bedeutet $=\!(x_1, \ldots, x_{n-1}, x_n)$, dass der Wert von x_n durch die Werte von $x_1, \ldots, x_{n-1}$ bestimmt wird.

Wir betrachten Fragmente modaler Dependence-Logik, die durch Beschränken der Menge erlaubter modaler und aussagenlogischer Operatoren definiert sind. Wir klassifizieren diese Fragmente in Bezug auf die Komplexität ihres Erfüllbarkeits- und Model-Checking-Problems. Für Erfüllbarkeit erhalten wir Komplexitätsgrade von P über NP, Σ_2^{P} und PSPACE bis hin zu NEXP, während wir die Fragmente für Model-Checking nur in Bezug auf ihre Praktikabilität klassifizieren, d.h. wir zeigen entweder NP-Vollständigkeit oder Enthaltensein in P.

Anschließend untersuchen wir die Erweiterung modaler Dependence-Logik um die sogenannte intuitionistische Implikation. Für diese Erweiterung klassifizieren wir wiederum die Fragmente in Bezug auf die Komplexität ihres Model-Checking-Problems. Hierbei erhalten wir Komplexitätsgrade von P über NP und coNP bis hin zu PSPACE.

Zuletzt analysieren wir noch erststufige Dependence-Logik, Independence-friendly-Logik und deren Zwei-Variablen-Fragmente. Wir beweisen, dass das Erfüllbarkeitsproblem für Zwei-Variablen-Dependence-Logik NEXP-vollständig ist, während es für Zwei-Variablen-Independence-friendly-Logik unentscheidbar ist; und benutzen dieses Resultat, um zu beweisen, dass letztere Logik zudem ausdrucksstärker als die vorherige ist.

Schlagworte: Dependence-Logik, Komplexität, Modallogik, Erfüllbarkeit, Model-Checking, Zwei-Variablen-Logik, Independence-friendly-Logik, Intuitionistische Logik

ABSTRACT

In this thesis (modal) dependence logic is investigated. It was introduced in 2007 by Jouko Väänänen as an extension of first-order (resp. modal) logic by the dependence operator $=(\cdot)$. For first-order (resp. propositional) variables $x_1, \dots, x_n$, $=(x_1, \dots, x_{n-1}, x_n)$ intuitively states that the value of x_n is determined by those of $x_1, \dots, x_{n-1}$.

We consider fragments of modal dependence logic obtained by restricting the set of allowed modal and propositional connectives. We classify these fragments with respect to the complexity of their satisfiability and model-checking problems. For satisfiability we obtain complexity degrees from P over NP, Σ_2^{P} and PSPACE up to NEXP, while for model-checking we only classify the fragments with respect to their tractability, i. e. we either show NP-completeness or containment in P.

We then study the extension of modal dependence logic by intuitionistic implication. For this extension we again classify the complexity of the model-checking problem for its fragments. Here we obtain complexity degrees from P over NP and coNP up to PSPACE.

Finally, we analyze first-order dependence logic, independence-friendly logic and their two-variable fragments. We prove that satisfiability for two-variable dependence logic is NEXP-complete, whereas for two-variable independence-friendly logic it is undecidable; and use this to prove that the latter is also more expressive than the former.

CHAPTER 1

INTRODUCTION

1.1 WHY DO WE NEED DEPENDENCE?

One of the purposes of formal logic is to aid in the translation of facts from natural language into mathematical language. Consider, for example, the following sentence:

"There are evil hackers."

This could be translated to the first-order formula

$$\exists x\,\big(\mathrm{evil}(x) \wedge \mathrm{hacker}(x)\big).$$

Now one could make the claim

"Every hacker named Eve or Mallory is evil."

And again we can translate to first-order logic:

$$\forall x\,\Big(\big(\mathrm{hacker}(x) \wedge \big(\mathrm{Eve}(x) \vee \mathrm{Mallory}(x)\big)\big) \rightarrow \mathrm{evil}(x)\Big)$$

A more general claim of this sort is the following:

"The degree of evilness of someone is determined by his/her name." (1.1)

But now we have a problem when translating to first-order logic since the concept of some arbitrary *dependence* or *determination* is not expressible in common first-order logic. We can state a fully specified dependence as above where we know that *hacker* together with *Eve or Mallory* implies *evil*. But when we only know that there is a dependence between variables or terms but do not know its details, i. e. in this case which names belong to which grades of evilness, then first-order logic is not expressive enough.

In first-order logic, dependence between variables is determined by the order in which the variables are quantified – and therefore is always linear. For example, when using game theoretic semantics to evaluate the formula

$$\forall x_0 \exists x_1 \forall x_2 \exists x_3\, \phi,$$

the choice for x_1 depends on the value of x_0 and the choice for x_3 depends on the value of both universally quantified variables x_0 and x_2. What we need is the possibility to express non-linear dependencies between variables – which cannot be expressed in first-order logic ($\mathcal{FO}$).

The first step in this direction was taken by Henkin [Hen61] with his *partially-ordered quantifiers*

$$\begin{pmatrix} \forall x_0 & \exists x_1 \\ \forall x_2 & \exists x_3 \end{pmatrix} \phi, \tag{1.2}$$

where x_1 depends only on x_0 and x_3 depends only on x_2.

The second step was taken by Hintikka and Sandu [HS89, Hin96] who introduced *independence-friendly logic* ($\mathcal{IF}$) which extends $\mathcal{FO}$ in terms of *slashed quantifiers*. For example, in

$$\forall x_0 \exists x_1 \forall x_2 \exists x_3 / \forall x_0\, \phi$$

the quantifier $\exists x_3/\forall x_0$ means that x_3 is *independent* of x_0 in the sense that a choice for the value of x_3 should not depend on what the value of x_0 is. The semantics of $\mathcal{IF}$ was first formulated in game theoretic terms and therefore $\mathcal{IF}$ can be regarded as a game theoretically motivated generalization of $\mathcal{FO}$. Whereas the semantic game of $\mathcal{FO}$ is a game of perfect information, the game of $\mathcal{IF}$ is a game of imperfect information. Later, the team semantics of $\mathcal{IF}$, also used in this thesis, was introduced by Hodges [Hod97a, Hod97b].

Dependence logic ($\mathcal{D}$), introduced by Väänänen [Vää07], is inspired by $\mathcal{IF}$-logic, but here the dependencies between variables are written in terms of atomic dependence formulas. For example, the partially-ordered quantifier (1.2) can be expressed in dependence logic as

$$\forall x_0 \exists x_1 \forall x_2 \exists x_3\, (=\!(x_2, x_3) \wedge \phi).$$

The atomic formula $=\!(x_2, x_3)$ has the explicit meaning that x_3 is completely determined by x_2 and nothing else. For x_1 on the other hand we do not need a dependence atom since it is quantified before x_2 and therefore automatically completely determined by x_0 alone. In general, functional dependence of the value of a term t_n from the values of the terms $t_1, \ldots, t_{n-1}$, denoted by $=(t_1, \dots, t_{n-1}, t_n)$, states that there is a function, say f, such that $t_n = f(t_1, \dots, t_{n-1})$ holds, i. e. the value of t_n is completely determined by those of $t_1, \dots, t_{n-1}$.

First-order logic with partially-ordered quantifiers, independence-friendly logic and dependence logic are all *conservative extensions* of first-order logic, i. e. they agree with $\mathcal{FO}$ on sentences which syntactically are $\mathcal{FO}$-sentences, and are expressively equivalent to *existential second-order logic* ($\mathcal{ESO}$) [End70, Wal70, Hod97b, Vää07].

Hence, reconsidering our hacker example (1.1), we can formalize it in any of the above extensions of first-order logic. In dependence logic we can write it as

$$\forall x \exists y \exists z \left(y = \text{evilness}(x) \wedge z = \text{name}(x) \wedge =(z, y) \right),$$

in $\mathcal{IF}$ as

$$\forall x \exists z \exists y / \forall x \left(y = \text{evilness}(x) \wedge z = \text{name}(x) \right)$$

and with a partially-ordered quantifier as

$$\begin{pmatrix} \forall x & \exists y & \exists z \\ \forall x' & \exists y' & \exists z' \end{pmatrix} \qquad \begin{aligned} &\big(y = \text{evilness}(x) \wedge z = \text{name}(x) \\ \wedge \quad & y' = \text{evilness}(x') \wedge z' = \text{name}(x') \\ \wedge \quad & z = z' \; \rightarrow \; y = y' \big). \end{aligned}$$

Note that although the statement can be expressed in all three logics its formulation is not equally intuitive in each one of them. With partially-ordered quantifiers we have to introduce additional variables (which are later identified with one another) and in $\mathcal{IF}$ we have to arrange the quantifiers in a specific order whereas in $\mathcal{D}$ we do not have any of such restrictions.

1.2 THE NATURE OF DEPENDENCE

Of course, dependence does not manifest itself in a single world, play, event or observation. Important for a dependence to make sense is a collection of such worlds, plays, events or observations. These collections are called *teams*. They are the basic objects in the definition of the semantics of dependence logic. A team can be a set of rounds in a game. Then $=(x_1, \dots, x_{n-1}, x_n)$ intuitively states that in each round move x_n is determined by moves $x_1, \dots, x_{n-1}$. A team can be a database. Then $=(x_1, \dots, x_{n-1}, x_n)$ intuitively states that in each line the value of attribute x_n is determined by the values of attributes $x_1, \dots, x_{n-1}$, i. e. x_n is functionally determined by $x_1, \dots, x_{n-1}$.

More formally, in first-order logic a team X is a set of assignments and $=(x_1, \dots, x_{n-1}, x_n)$ states that in each assignment the value of x_n is determined by the values of $x_1, \dots, x_{n-1}$, i. e. there is a function $f \colon A^{n-1} \to A$ (where A is the universe of a first-order structure) such that for all $s \in X$ it holds that $s(x_n) = f(s(x_1), \dots, s(x_{n-1}))$. Dependence logic ($\mathcal{D}$) is defined by simply adding these dependence atoms to usual first-order logic [Vää07] and is a conservative extension of the latter.

In modal logic a team is a set of worlds in a Kripke structure and $=(p_1, \dots, p_{n-1}, p_n)$ states that in each of these worlds the value of the propositional variable p_n is determined by the values of $p_1, \dots, p_{n-1}$, i. e. there is a Boolean function $f \colon \{\top, \bot\}^{n-1} \to \{\top, \bot\}$ that determines the value of p_n from the values of $p_1, \dots, p_{n-1}$ for all worlds in the team. Modal dependence logic ($\mathcal{MDL}$) is the conservative extension of modal logic defined by introducing dependence atoms to modal logic [Vää08].

1.3 COMPUTATIONAL COMPLEXITY

In this thesis we will investigate fragments of first-order as well as modal dependence logic from a computational point of view, i. e. we will determine the difficulty of computational problems involving logical formulas. Naturally, the question that arises is: What, precisely, do we mean by *difficulty*? To answer this question we use methods from the field of computational complexity which will be introduced in the following.

When designing an algorithm to solve a problem, it is, of course, important whether your algorithm needs to run a minute or a year to solve the problem. If you have only one problem to solve you can simply specify the ressources needed by the algorithm by noting its runtime and the memory space it uses. But now imagine that you are designing an algorithm to solve a type of problems, e. g. an algorithm to compute the fastest car route from city A to city B. Now the time and space needed by the algorithm depend on the distance between the two cities, the number of citites in between them and many other things.

One way to specify the time and space of a generic algorithm is to express the worst-case runtime and memory space needed by the algorithm as a function of the size of the given problem. Here, *size* can, for example, mean the number of nodes in a graph, the number of rows in a database or the number of streets on a map that includes both city A and city B. The *computational complexity* of a problem type can then be specified by finding an optimal algorithm to solve it and examining the algorithm's worst-case time and space needs as a function of the input size.

The probably most important complexity class definable in this way is the class P of all problems for which there is an algorithm solving them whose runtime is bounded by a polynomial in the input size. Another important class is EXP which is defined analogous to P but instead of a polynomial function there only has to be an exponential function for the runtime bound.

For these two classes (as for many other pairs of classes) there is a fundamental difference between the complexity of a problem A in class P and a problem B in class EXP. Assume, for example, that for a given input size the optimal algorithms for both problems can compute a solution in one minute. Now, if we increase the input size by one unit, the algorithms for the problems will, for example, both take two minutes. But if we further increase the input size by one more unit then problem A will typically be solved in three minutes while problem B will take four minutes. And by each further incrementation of the input size, problem A will take one more minute while the time needed to solve problem B will double. So the latter has a fundamentally worse asymptotic runtime than the former.

This example demonstrates that a single complexity class typically covers a wide range of concrete runtime or space usage functions and that the differences between two classes are usually of a fundamental nature which cannot be eliminated by simply using faster computers or optimized algorithms.

1.4 MODAL DEPENDENCE LOGIC

Väänänen [Vää08] introduced both an inductive semantics and an equivalent game-theoretic semantics for modal dependence logic. Sevenster [Sev09] proved that on singleton teams, i. e. teams which contain only one world, there is a translation from $\mathcal{MDL}$ to usual modal logic while on arbitrary teams there is no such translation. Sevenster also initiated the complexity-theoretic study of modal dependence logic by proving that the satisfiability problem of $\mathcal{MDL}$ is complete for the class NEXP of all problems decidable by a nondeterministic Turing machine in exponential time.

In this thesis, we continue the work of Sevenster by presenting a more thorough study on complexity questions related to $\mathcal{MDL}$. We will systematically investigate fragments of $\mathcal{MDL}$ by restricting the propositional and modal operators allowed in the language. This method of classifying the complexity of logic related problems goes back to Lewis who used this method for the satisfiability problem of propositional logic [Lew79]. Recently it was, for example, used by Hemaspaandra et al. for the satisfiability problem of modal logic [Hem05, HSS10] and by Meier et al. for the satisfiability problem of temporal logic [MMTV09]. The motivation for this approach is that by a systematic study of all fragments of a logic one might find a fragment with efficient algorithms but still high enough expressivity to be useful in practice. On the other hand, this systematic approach usually leads to insights into the sources of hardness, i. e. the exact components of the logic that make satisfiability, model checking, etc. hard.

We follow the same approach here. We consider all subsets of modal operators $\Box$, $\Diamond$ and propositional operators $\wedge$, $\vee$, $\neg$ (atomic negation), $\top$, $\bot$ (the Boolean constants true and false), i. e. we study exactly those operators considered by Väänänen [Vää08], and each time examine the satisfiability problem and the model checking problem of $\mathcal{MDL}$ restricted to formulas built only by operators from the chosen subset. Here, by *satisfiability* we mean the problem where a formula is given and the task is to decide whether there is a Kripke structure satisfying the formula. By *model checking* we mean the problem where a formula, a Kripke structure and a team are given and the task is to decide whether the Kripke structure and the team satisfy the formula.

We also extend the logical language of [Vää08] by adding classical disjunction (denoted here by $\varovee$) besides the usual dependence disjunction. Connective $\varovee$ was already considered by Sevenster (he denoted it by $\bullet$), but not from a computational point of view. Furthermore it seems natural to not only restrict modal and propositional operators but to also impose restrictions on the dependence atoms. We consider one such restriction, where we limit the arity of the dependence atoms, i. e. the number n of variables $p_1, \dots, p_n$ by which q has to be determined to satisfy the formula $=(p_1, \dots, p_n, q)$, to a fixed upper bound $k \geqslant 0$ (the logic is then denoted by $\mathcal{MDL}_k$).

We include both, the classical disjunction and the arity restricted dependence atoms, into the set of operators which we systematically restrict. Then we analyze the complexity of the satisfiability problem and the model checking problem of $\mathcal{MDL}$ and $\mathcal{MDL}_k$ for all subsets of operators studied by Väänänen and Sevenster.

1.5 INTUITIONISTIC DEPENDENCE LOGIC

In classical logic (modal as well as first-order and propositional) there is a well-defined canonical notion of *implication* which is defined by interpreting $\phi \rightarrow \psi$ as a shortcut for $\neg\phi \vee \psi$. In dependence logic, however, there is no such canonical notion. The reason for this is that $\neg\phi$ is not well-defined for an arbitrary formula ϕ since negation is only atomic in dependence logic. It is, of course, possible to define arbitrary negation $\neg\phi$ to mean the dual formula ϕ^{d} obtained from $\neg\phi$ by pushing the negation down to the atomic level by use of de Morgan's law.

However, when using this syntactically-defined non-atomic negation the obtained notion of implication misses some of the usually desired properties. For example, it is possible that in a team neither ϕ nor ψ holds but neither does the formula $\neg\phi \vee \psi$. Therefore Abramsky and Väänänen [AV09] have investigated two other notions of implication, namely *linear implication* $\multimap$ and *intuitionistic implication* $\rightarrow$. The latter satisfies axioms of intuitionistic logic and is defined by $\phi \rightarrow \psi$ being satisfied in a team iff in all subteams where ϕ is satisfied it also holds that ψ is satisfied.

Yang [Yan11] proved that first-order dependence logic extended by intuitionistic implication has the same expressive power as full second-order logic on the level of sentences. Additionally, this still holds for the fragment called *intuitionistic dependence logic* ($\mathcal{IDL}$) which only uses quantifiers, $\wedge$, $\otimes$, $\neg$, $\rightarrow$ and dependence atoms, i. e. it misses $\vee$.

In this thesis we consider modal dependence logic extended with intuitionistic implication, called *modal intuitionistic dependence logic* ($\mathcal{MIDL}$). We follow the same approach as for $\mathcal{MDL}$ and investigate the computational complexity of the model checking problem of fragments of $\mathcal{MIDL}$ obtained by using only subsets of the operators. Amongst others we discuss a natural variant of first-order $\mathcal{IDL}$, namely *propositional intuitionistic dependence logic* ($\mathcal{PIDL}$) which in our setting can be identified with $\mathcal{MIDL}$ without modalities and without disjunction $\vee$.

1.6 TWO-VARIABLE LOGIC

The satisfiability problem of first-order logic $\mathcal{FO}$ was shown to be undecidable in [Chu36, Tur36] and, ever since, logicians have been searching for decidable fragments of $\mathcal{FO}$. Henkin [Hen67] was the first to consider the logics $\mathcal{FO}^k$, i. e. the fragments of first-order logic with only k variables. The fragments $\mathcal{FO}^k$ for $k \geqslant 3$ were easily seen to be undecidable but the case for $k = 2$ remained open. Earlier, Scott [Sco62] had shown that $\mathcal{FO}^2$ without equality is decidable and then Mortimer [Mor75] extended the result to $\mathcal{FO}^2$ with equality and showed that every satisfiable $\mathcal{FO}^2$ formula has a model whose size is at most doubly exponential in the length of the formula. His result established that the satisfiability and finite satisfiability problems of $\mathcal{FO}^2$ are contained in NEEXP. Finally, Grädel, Kolaitis and Vardi [GKV97] improved the result of Mortimer by establishing that every satisfiable $\mathcal{FO}^2$ formula has a model of exponential size. Furthermore, they showed that the satisfiability problem of $\mathcal{FO}^2$ is NEXP-complete.

Since then, the decidability of the satisfiability problem of various extensions of $\mathcal{FO}^2$ has been studied (e. g. [GOR97b, GO99, EVW02, KO05]). One such extension, $\mathcal{FOC}^2$, is acquired by extending $\mathcal{FO}^2$ with counting quantifiers $\exists^{\geqslant k}$. The meaning of a formula of the form $\exists^{\geqslant k} x\, \phi(x)$ is that $\phi(x)$ is satisfied by at least k distinct elements. The satisfiability problem of the logic $\mathcal{FOC}^2$ was shown to be decidable by Grädel et al. [GOR97a] and shown to be in NEEXP by Pacholski et al. [PST97]. Finally, Pratt-Hartmann [PH05] established that the problem is NEXP-complete.

In this thesis we study the decidability and complexity of the satisfiability problems for the two-variable fragments of independence-friendly logic and dependence logic. For this purpose we will use the result of Pratt-Hartmann to determine the complexity of satisfiability for two-variable dependence logic.

1.7 RESULTS

In Section 4.1 we completely classify the complexity of the satisfiability problem of all fragments of $\mathcal{MDL}$ defined by taking only some of the operators and constants $\Box$, $\Diamond$, $\wedge$, $\vee$, $\varovee$, $\neg$, $\top$, $\bot$ and $=\!(\cdot)$.

One of our main and technically most involved contributions addresses a fragment that has been called *Poor Man's Logic* in the literature on modal logic [Hem01], i. e. the language without disjunction $\vee$. We show that for unbounded arity dependence logic we still have full complexity (Theorem 4.5), i. e. we show that Poor Man's Dependence Logic is NEXP-complete. If we also forbid negation then the complexity drops down to $\Sigma_2^{\mathsf{P}} (= \mathsf{NP}^{\mathsf{NP}})$, i. e. Monotone Poor Man's Dependence Logic is Σ_2^{P}-complete (Theorem 4.4, but note that we need $\varovee$ here). And if we, instead of forbidding negation, restrict the logic to only contain dependence atoms of arity less or equal k for a fixed $k \geqslant 3$ then the complexity drops to $\Sigma_3^{\mathsf{P}} (= \mathsf{NP}^{\Sigma_2^{\mathsf{P}}})$, i. e. bounded arity Poor Man's Dependence Logic is Σ_3^{P}-complete (Corollary 4.10b).

All of our complexity results are summarized in Table 4.1 for dependence atoms of unbounded arity and in Table 4.2 for dependence atoms whose arity is bounded by a fixed $k \geqslant 3$.

In Section 4.2 we classify the complexity of the model checking problem of fragments of $\mathcal{MDL}$ with unbounded as well as bounded arity dependence atoms. For plain modal logic this problem is solvable in P as shown by Clarke et al. [CES86]. A detailed complexity classification for the model checking problem over fragments of modal logic was given by Beyersdorff et al. [BMM$^+$11] (who investigate the temporal logic $\mathcal{CTL}$ which contains plain modal logic as a special case).

In the case of $\mathcal{MDL}$ it turns out that model checking is NP-complete in general and that this still holds for several seemingly quite weak fragments of $\mathcal{MDL}$, e. g. the one without modalities or the one where nothing except dependence atoms and $\Diamond$ is allowed. Interestingly, this also holds for the case where only both disjunctions $\vee$ and $\otimes$ are allowed and not even dependence atoms occur.

We are able to determine the tractability of each fragment except the one where formulas are built from atomic propositions and unbounded dependence atoms only by dependence disjunction and negation. In each of the other cases we either show NP-completeness or show that the model checking problem admits an efficient (deterministic polynomial time) solution.

For the restriction to bounded arity dependence atoms, model checking remains NP-complete in general but for the fragment with only the $\Diamond$ operator allowed this does not hold any more. In this case either $\wedge$ or $\vee$ is needed to still get NP-hardness.

In Table 4.3 we list all of our complexity results for the cases with unbounded arity dependence atoms and in Table 4.4 for the cases with bounded arity.

In Chapter 5 we extend our classification from Section 4.2 to include intuitionistic implication into the set of operators, i. e. we study the complexity of model checking for $\mathcal{MIDL}$ and its fragments. We prove that model checking for $\mathcal{MIDL}$ in general is PSPACE-complete but for the $\mathcal{MIDL}$ fragment where formulas are not allowed to contain $\Diamond$ or $\vee$ the problem turns out to be coNP-complete. In particular, model checking for $\mathcal{PIDL}$ is coNP-complete. Our detailed results are listed in Table 5.1.

In Chapter 6 we examine the expressiveness, satisfiability and finite satisfiability for bounded-variable $\mathcal{IF}$-logic and dependence logic. We show that there is an effective translation from $\mathcal{D}^2$ to $\mathcal{IF}^2$ (Lemma 6.1) and from $\mathcal{IF}^2$ to $\mathcal{D}^3$ (Lemma 6.2). We also show that $\mathcal{IF}^2$ is strictly more expressive than $\mathcal{D}^2$ (Proposition 6.5). This result is a by-product of our proof that the satisfiability problem of $\mathcal{IF}^2$ is undecidable (Theorem 6.19 shows Π^0_1-completeness). The proof can be adapted to the context of finite satisfiability, i. e. the problem of determining for a given formula ϕ whether there is a finite structure $\mathfrak{A}$ such that $\mathfrak{A} \models \phi$ holds (Theorem 6.23 shows Σ_1^0-completeness). The undecidability proofs are based on tiling arguments. Finally, we study the decidability of the satisfiability and finite satisfiability problems of $\mathcal{D}^2$. For this purpose we reduce the problems to the (finite) satisfiability problem of $\mathcal{FOC}^2$ (Theorem 6.24) and thereby show that they are NEXP-complete (Theorem 6.25).

1.8 PUBLICATIONS

Section 4.1 is based on [LV10] – although Section 4.1.3 about the bounded arity cases is new. Section 4.2 is based on [EL12] – while the investigation of the $\ovee$ operator is new (Section 4.2.3 and new version of Theorem 4.24). Chapter 5 contains unpublished work with Fan Yang and Johannes Ebbing. Finally, Chapter 6 is based on [KKLV11] – while Theorem 6.11 and the proofs in Section 6.2.1 are new.

CHAPTER 2

PRELIMINARIES

2.1 PREDICATE LOGIC

We assume familiarity with the basic notions of first- and second-order logic and thus will not explain what a vocabulary or a structure is. The interested reader may refer to any introductory logic textbook, e. g. [EFT94]. We will, however, restate the semantics of first-order logic in terms of team semantics since this will be used in the next chapter to define the semantics of (first-order) dependence logic.

First, let us quickly recall the syntax of first-order logic.

Definition 2.1 (Syntax of first-order logic). Let τ be a first-order vocabulary, $t_1, \dots, t_n$ arbitrary τ-terms, R an arbitrary relation symbol in τ (of arity n) and x an arbitrary first-order variable. Then $\mathcal{FO}$ is the set of all formulas built by the rules

$$\begin{aligned} \phi \quad ::= \quad & \top \mid \bot \mid R(t_1,\dots,t_n) \mid \neg R(t_1,\dots,t_n) \mid t_1 = t_2 \mid \neg t_1 = t_2 \mid \\ & \phi \wedge \phi \mid \phi \vee \phi \mid \forall x\phi \mid \exists x\phi. \end{aligned}$$

⌟

Note that w. l. o. g. we only define formulas in negation normal form. The rationale for this will become clear in the next chapter when we see that for dependence logic we have to use negation normal form since negation is only properly defined for atomic formulas.

To define team semantics we first introduce the concept of a *team*. Let $\mathfrak{A}$ be a *model* (or *structure*) with domain A (in the future, we will assume that if $\mathfrak{A}$ (resp. $\mathfrak{B}$, $\mathfrak{C}$,...) is a model then A (resp. B, C,...) is its domain). *Assignments* over $\mathfrak{A}$ are finite functions that map variables to elements of A. The value of a term t in an assignment s is denoted by $t^{\mathfrak{A}}\langle s\rangle$. If s is an assignment, x is a variable and $a \in A$ then $s(a/x)$ denotes the assignment (with the domain $\mathrm{dom}(s) \cup \{x\}$) which agrees with s everywhere except that it maps x to a.

Let $\{x_1, \ldots, x_k\}$ be a finite (possibly empty) set of variables. A *team* X of A with domain $\mathrm{dom}(X) = \{x_1, \ldots, x_k\}$ is a set of assignments from the variables $\{x_1, \ldots, x_k\}$ into A. We denote by $\mathrm{rel}(X)$ the k-ary relation of A corresponding to X:

$$\mathrm{rel}(X) := \{(s(x_1), \ldots, s(x_k)) \mid s \in X\}.$$

If X is a team of A and $F\colon X \to A$, we use to denote the team

$$\{s(F(s)/x) \mid s \in X\}$$

and for the team

$$\{s(a/x) \mid s \in X \text{ and } a \in A\}.$$

If ϕ and θ are formulas and ψ is a subformula of ϕ then we define $\phi(\theta/\psi)$ to be the formula generated from ϕ by *substituting* all occurrences of ψ with θ.

Definition 2.2 (Team semantics of $\mathcal{FO}$). Let $\mathfrak{A}$ be a model and let X be a team of A. The *satisfaction relation* $\mathfrak{A} \models_X \phi$ is defined as follows:

- If ϕ is an atomic formula then $\mathfrak{A} \models_X \phi$ iff for all $s \in X$: $\mathfrak{A}, s \models \phi$ (in the usual single-assignment based semantics).
- If ψ is atomic then $\mathfrak{A} \models_X \neg\psi$ iff for all $s \in X$: $\mathfrak{A}, s \not\models \psi$.
- $\mathfrak{A} \models_X \psi \wedge \phi$ iff $\mathfrak{A} \models_X \psi$ and $\mathfrak{A} \models_X \phi$.
- $\mathfrak{A} \models_X \psi \vee \phi$ iff there exist teams Y and Z such that $X = Y \mathbin{\dot\cup} Z$, $\mathfrak{A} \models_Y \psi$ and $\mathfrak{A} \models_Z \phi$.
- $\mathfrak{A} \models_X \exists x\psi$ iff $\mathfrak{A} \models_{X(F/x)} \psi$ for some $F\colon X \to A$.
- $\mathfrak{A} \models_X \forall x\psi$ iff $\mathfrak{A} \models_{X(A/x)} \psi$.

Above, we assume that the domain of X contains $\mathrm{Fr}(\phi)$, i. e. it contains all variables occurring in ϕ outside the scope of a quantifier. Finally, a sentence ϕ is true in a model $\mathfrak{A}$ ($\mathfrak{A} \models \phi$) iff $\mathfrak{A} \models_{\{\emptyset\}} \phi$ holds. ⌟

Remark 2.3. *Note that this team semantics coincides with the usual single-assignment based semantics for first-order logic, i. e. for all structures $\mathfrak{A}$, formulas $\phi \in \mathcal{FO}$ and assignments $s\colon \mathrm{Fr}(\phi) \to A$ it holds that*

$$\mathfrak{A} \models_{\{s\}} \phi \quad \textit{iff} \quad \mathfrak{A}, s \models_{\mathcal{FO}} \phi.$$

For second-order logic we assume the usual single-assignment based semantics and only recall the syntax here.

Definition 2.4 (Syntax of second-order logic). The syntax of $\mathcal{SO}$ extends the syntax of $\mathcal{FO}$ by the rules

$$\phi ::= \exists S\phi \mid \forall S\phi,$$

where S is a second-order variable, i. e. it is interpreted by a relation (with an a priori given arity) and used in the inner formula as if it belonged to the vocabulary. ⌟

The following fragment of $\mathcal{SO}$ will be of special interest.

Definition 2.5 ($\mathcal{ESO}$). *Existential second-order logic ($\mathcal{ESO}$)* consists of all $\mathcal{SO}$-formulas that are of the form $\exists R_1 \ldots \exists R_n \phi$ for a $\mathcal{FO}$-formula ϕ. ⌟

2.1.1 FRAGMENTS OF FIRST-ORDER LOGIC

For first-order logic we also investigate fragments where only a fixed number of names for variables are allowed inside a formula.

Definition 2.6 ($\mathcal{FO}^k$). Let $k > 0$ and τ a relational vocabulary, i. e. τ does not contain function or constant symbols. Then *k-variable first-order logic* ($\mathcal{FO}^k$) is the set of all $\mathcal{FO}$-formulas that contain no more than k distinct variables (we will usually use $x_1, \ldots, x_k$ and in the case $k = 2$ we use x and y). ⌟

Note that the above definition does not forbid requantification of variables, e. g. $\exists x \exists y(Pxy \wedge \exists x Qxy)$ is in $\mathcal{FO}^2$.

In common first-order logic there are only two quantifiers, one asking about the existence of *at least one* element with a certain property and the other one, the dual, stating that the property holds for all elements, i. e. its complement holds for *less than one* element.

A natural generalization of this is the introduction of *counting quantifiers* $\exists^{\geqslant k}$ asking about the existence of *at least k* pairwise-different elements. It is possible to define $\exists^{\geqslant k}$ for any $k \in \mathbb{N}$ with the ordinary $\exists$ quantifier by the translation

$$\exists^{\geqslant k} x\, \phi(x) \quad \mapsto \quad \exists x_1 \ldots \exists x_k \Big(\bigwedge_{\substack{i,j \in \{1,\ldots,k\},\\ i \neq j}} x_i \neq x_j \wedge \bigwedge_{i=1}^{k} \phi(x_i) \Big).$$

In the case of $\mathcal{FO}^k$ it is, however, no longer possible to define $\exists^{\geqslant k+1}$. Therefore we will investigate the following extension of $\mathcal{FO}^k$.

Definition 2.7 ($\mathcal{FOC}^k$). k-variable first-order logic with counting ($\mathcal{FOC}^k$) is the extension of $\mathcal{FO}^k$ obtained by allowing the counting quantifiers $\exists^{\geqslant\ell}$ (for all $\ell \in \mathbb{N}$) as well as their negations $\exists^{<\ell}$. ⌟

For an introduction into bounded-variable first-order logic with counting we refer to [Ott97].

2.2 MODAL LOGIC

We will only briefly restate the definition of modal logic here. For a more in-depth introduction the reader may refer to [BdRV02].

Definition 2.8 (Syntax of modal logic). Let PROP be an arbitrary countable set (of atomic propositions). Then $\mathcal{ML}$ is the set of all formulas ϕ built by the rules

$$\phi ::= \top \mid \bot \mid p \mid \neg p \mid \phi \wedge \phi \mid \phi \vee \phi \mid \Box\phi \mid \Diamond\phi,$$

where $p \in$ PROP.

$\mathcal{CL}$ (*classical logic*) is the set of all formulas of $\mathcal{ML}$ that neither contain $\Box$ nor $\Diamond$ operators, i. e. $\mathcal{CL}$ is the set of all purely-propositional Boolean formulas. ⌟

We sometimes write $\Box^k$ (resp. $\Diamond^k$) for $\underbrace{\Box\Box\ldots\Box}_{k\text{ times}}$ (resp. $\underbrace{\Diamond\Diamond\ldots\Diamond}_{k\text{ times}}$). Note that we have defined $\top$ and $\bot$ as parts of the language although we could equivalently have defined them as abbreviations for $p \vee \neg p$ and $p \wedge \neg p$, respectively. The rationale for this is that we will forbid negation and/or disjunction in parts of Section 4.1 but still want to allow the constants.

Note that we define negation to be only atomic, i. e. it is only defined for atomic propositions. Although in the literature negation is usually defined for arbitrary formulas, our definition is in fact not a restriction of this general case. This is due to the fact that arbitrary negation can be defined in terms of dual formulas by

$$\neg\phi := \phi^{\mathrm{d}},$$

where dual formulas are defined as follows.

Definition 2.9 (Dual formulas). Let $\phi \in \mathcal{ML}$. Then the *dual* of a formula is defined by the following translation $\phi \mapsto \phi^{\mathrm{d}}$:

$$\begin{array}{rcl} \top & \mapsto & \bot \\ \bot & \mapsto & \top \\ p & \mapsto & \neg p \\ \neg p & \mapsto & p \\ \psi \wedge \theta & \mapsto & \psi^{\mathrm{d}} \vee \theta^{\mathrm{d}} \\ \psi \vee \theta & \mapsto & \psi^{\mathrm{d}} \wedge \theta^{\mathrm{d}} \\ \Box\psi & \mapsto & \Diamond\psi^{\mathrm{d}} \\ \Diamond\psi & \mapsto & \Box\psi^{\mathrm{d}}. \end{array}$$

Note that an analogous defintion of dual formulas can be given for first-order formulas. ⌟

We will define the semantics of $\mathcal{ML}$ via a translation to $\mathcal{FO}^2$.

Definition 2.10. We define a translation $\phi \mapsto \widetilde{\phi}(x)$ from $\mathcal{ML}$ to $\mathcal{FO}^2$ as follows:

$$\begin{array}{rcl} \top & \mapsto & \top \\ \bot & \mapsto & \bot \\ p & \mapsto & P(x) \\ \neg p & \mapsto & \neg P(x) \\ \psi \wedge \theta & \mapsto & \widetilde{\psi}(x) \wedge \widetilde{\theta}(x) \\ \psi \vee \theta & \mapsto & \widetilde{\psi}(x) \vee \widetilde{\theta}(x) \\ \Box\psi & \mapsto & \forall y\,\big(R(x,y) \rightarrow \widetilde{\psi}(y)\big) \\ \Diamond\psi & \mapsto & \exists y\,\big(R(x,y) \wedge \widetilde{\psi}(y)\big). \end{array}$$

⌟

Note that if ϕ is a $\mathcal{ML}$-formula over the atomic propositions $\textsc{Prop} = \{p_1, p_2, \ldots\}$ then $\widetilde{\phi}$ is a $\mathcal{FO}^2$-formula over the vocabulary $\tau_{\textsc{Prop}} := \{R, P_1, P_2, \ldots\}$.

Definition 2.11 (Team semantics of modal logic). Let $\phi \in \mathcal{ML}$, $\mathfrak{A}$ a $\tau_{\textsc{Prop}}$-structure and $T \subseteq A$ a *team*. Then we say that $\mathfrak{A}$ in T *satisfies* ϕ ($\mathfrak{A}, T \models \phi$) if and only if $\mathfrak{A} \models_X \widetilde{\phi}(x)$ where $X := \{\{x \mapsto a\} \mid a \in T\}$, i. e. X is the first-order team that has one unary assignment $\{x \mapsto a\}$ for each element a in T. ⌟

Note that in the above definition we still call T a *team* of $\mathfrak{A}$ although it is a set of elements rather than a set of assignments.

The structure $\mathfrak{A}$ is often expressed in the form of a *Kripke structure* (or *frame*) – which is nothing else then a first-order $\tau_{\textsc{Prop}}$-structure with a special notation for representing the unary relations.

Definition 2.12 (Kripke structure). Let $\textsc{Prop}$ be a countable set of *atomic propositions*. Then a $\textsc{Prop}$-*Kripke structure* is a tuple $K = (S, R, \pi)$ where S is an arbitrary non-empty set of *worlds* or *states*, $R \subseteq S \times S$ is the *accessibility relation* and $\pi \colon S \to \mathfrak{P}(\textsc{Prop})$ is the *labeling function*. ⌟

The corresponding first-order $\tau_{\textsc{Prop}}$-structure $\widetilde{K}$ has universe S and contains the binary relation R and the unary relations $P_1, P_2, \ldots$ defined by $P_i := \{s \mid p_i \in \pi(s)\}$.

Note that this team semantics via translation to first-order logic coincides with the usual single-assignment non-translational semantics for modal logic, i. e. for all Kripke structures $K = (S, R, \pi)$, formulas $\phi \in \mathcal{MDL}$ and worlds $s \in S$ it holds that

$$K, \{s\} \models \phi \quad \text{iff} \quad K, s \models_{\mathcal{ML}} \phi.$$

For any team T of a Kripke model K, we define

$$R(T) = \{s \in K \mid \exists s' \in T \text{ such that } (s', s) \in R\}.$$

In the case that $T = \{s\}$, we write $R(s)$ instead of $R(\{s\})$. Elements in $R(s)$ are called *successors* of s. Furthermore we define

$$\langle T \rangle_R = \{T' \mid T' \subseteq R(T) \text{ and for all } s \in T \text{ with } R(s) \neq \emptyset\colon R(s) \cap T' \neq \emptyset\}.$$

If R is clear from the context we sometimes just write $\langle T \rangle$. Elements in $\langle T \rangle$ are called successor teams. Clearly, $R(T) \in \langle T \rangle$.

2.3 COMPLEXITY THEORY

We assume familiarity with the basic notions from computational complexity theory. An introduction to this can, for example, be found in [AB09] or in [Pap94]. We will just briefly recall the relevant complexity classes and results.

2.3.1 IMPORTANT CLASSES

Definition 2.13 (P, NP, PSPACE, EXP, NEXP). P (resp. NP) is the class of all (decision) problems, i. e. "yes-or-no-questions", solvable by a deterministic (resp. non-deterministic) Turing machine in polynomial time. Analogously, EXP (resp. NEXP) contains all problems solvable (non-)deterministically in exponential time and PSPACE contains all problems solvable in polynomial space. ⌟

Definition 2.14 (PH, Σ_k^{P}, Π_k^{P}, AP). The *polynomial hierarchy* is defined as

$$\mathsf{PH} := \bigcup_{k=1}^{\infty} \Sigma_k^{\mathsf{P}}$$

with

$$\begin{aligned} \Sigma_0^{\mathsf{P}} &:= \Pi_0^{\mathsf{P}} := \mathsf{P}, \\ \Sigma_{k+1}^{\mathsf{P}} &:= \mathsf{NP}^{\Sigma_k^{\mathsf{P}}} \text{ and} \\ \Pi_{k+1}^{\mathsf{P}} &:= \mathsf{coNP}^{\Sigma_k^{\mathsf{P}}}, \end{aligned}$$

where $\mathsf{NP}^{\mathcal{C}}$ describes the class of all problems solvable by a non-deterministic *oracle Turing machine*, using a problem from class $\mathcal{C}$ as oracle, in polynomial time and

$$A \in \mathsf{co}\mathcal{C} \quad \text{iff} \quad \bar{A} := \{x \mid x \notin A\} \in \mathcal{C}.$$

Equivalently, PH can be defined as the class of all problems for which there is an *alternating Turing machine* which decides the problem in polynomial running time and for which there is a $k \in \mathbb{N}$ such that for all inputs x the machine does not alternate between guessing modes more than k times when started with input x. Note that the maximum number of alternations, $k \in \mathbb{N}$, is arbitrary but fixed for the problem and thus must not depend on the input given to the machine. If this restriction is dropped we get the class AP of all problems for which there is an alternating Turing machine deciding the problem in polynomial running time. In [CKS81] it was shown that AP = PSPACE. ⌟

Definition 2.15 (Σ_1^0, Π_1^0, decidable). Σ_1^0 is the class of all decision problems A for which there is a Turing machine that, given input x, holds in an accepting state if $x \in A$ and runs infinitely long if $x \notin A$. Π_1^0 is defined as $\mathsf{co}\Sigma_1^0$.

A problem is said to be *decidable* iff there is a Turing machine that solves it, i. e. for all inputs it holds with the correct answer after a finite number of computation steps. ⌟

Figure 2.1 shows an inclusion diagram of all of the above complexity classes.

We will later need the *complexity operator* $\exists\cdot$. If $\mathcal{C}$ is an arbitrary complexity class then $\exists\cdot\mathcal{C}$ denotes the class of all sets A for which there is a set $B \in \mathcal{C}$ and a polynomial p such that for all x,

$$x \in A \quad \text{iff} \quad \text{there is a } y \text{ with } |y| \leqslant p(|x|) \text{ and } \langle x, y\rangle \in B.$$

Note that for every class $\mathcal{C}$, $\exists{\cdot}\mathcal{C} \subseteq \mathsf{NP}^{\mathcal{C}}$. However, the converse does not hold in general. We will only need the following facts: $\exists{\cdot}\mathsf{coNP} = \Sigma_2^{\mathsf{P}}$, $\exists{\cdot}\Pi_2^{\mathsf{P}} = \Sigma_3^{\mathsf{P}}$, $\exists{\cdot}\mathsf{PSPACE} = \mathsf{PSPACE}$ and $\exists{\cdot}\mathsf{NEXP} = \mathsf{NEXP}$.

2.3.2 REDUCIBILITY AND COMPLETENESS

Definition 2.16. Let C be a countable set and $A, B \subseteq C$. Then A is *polynomial-time many-one reducible* to B, in symbols $A \leqslant_{\mathrm{m}}^{\mathsf{P}} B$, iff there is a *reduction* function $f\colon C \to C$ such that f is computable in polynomial time and for all $x \in C$ it holds that $x \in A$ iff $f(x) \in B$.

We write $A \equiv_{\mathrm{m}}^{\mathsf{P}} B$ iff both $A \leqslant_{\mathrm{m}}^{\mathsf{P}} B$ and $B \leqslant_{\mathrm{m}}^{\mathsf{P}} A$ hold. ⌟

Note that most complexity classes $\mathcal{C}$ with $\mathsf{P} \subseteq \mathcal{C}$ are closed under $\leqslant_{\mathrm{m}}^{\mathsf{P}}$, i. e. if $A \leqslant_{\mathrm{m}}^{\mathsf{P}} B$ and $B \in \mathcal{C}$ then also $A \in \mathcal{C}$. This holds for all classes relevant to us.

Definition 2.17. Let A be a computational problem and let $\mathcal{C}$ be a complexity class with $\mathsf{P} \subseteq \mathcal{C}$. Then A is called *$\mathcal{C}$-hard* (w. r. t. $\leqslant_{\mathrm{m}}^{\mathsf{P}}$-reductions) iff for all $B \in \mathcal{C}$ it holds that $B \leqslant_{\mathrm{m}}^{\mathsf{P}} A$. A is called *$\mathcal{C}$-complete* (w. r. t. $\leqslant_{\mathrm{m}}^{\mathsf{P}}$-reductions) iff $A \in \mathcal{C}$ and A is $\mathcal{C}$-hard. ⌟

2.4 LOGICAL PROBLEMS

Whenever one is investigating a logic there are several basic problems which are naturally interesting. We will now introduce three of them – from the complexity theory point of view.

2.4.1 SATISFIABILITY

The first of the problems is the satisfiability of a given formula, i. e. the question whether there exists a structure that satisfies the formula. This question for example arises in the context of system design – when a formula is used to specify certain properties and one wants to know whether there is a system with such properties. Also, it is often the case that many other problems related to a logic can be reduced to its satisfiability problem.

Definition 2.18. If $\mathcal{L}$ is a logic and its semantics, i. e. the satisfaction of formulas, is defined over a class of structures $\mathcal{C}$ then its *satisfiability problem* is defined as

Problem: $\mathcal{L}$-$\mathcal{C}$-SAT

Input: A formula $\phi \in \mathcal{L}$.
Question: Is there a structure $\mathfrak{A} \in \mathcal{C}$ such that $\mathfrak{A} \models \phi$ holds?

If $\mathcal{C}$ is clear from the context we just write $\mathcal{L}$-SAT instead of $\mathcal{L}$-$\mathcal{C}$-SAT. The finite satisfiability problem $\mathcal{L}$-FINSAT is the analogue of $\mathcal{L}$-SAT in which we require the structure $\mathfrak{A}$ to be finite.

Sometimes the formal definition of the satisfaction relation entails the necessity to not only have a structure but also an element or assignment (or a set of elements or assignments) from the structure to satisfy the formula. The question then becomes

> Is there a structure $\mathfrak{A} \in \mathcal{C}$ and an element $a \in A$ / an assignment $s\colon \mathrm{dom}(\phi) \to A$ (resp. a set $T \subseteq A$ of elements / X of assignments) such that $M, a \models \phi$ / $M, s \models \phi$ (resp. $M, T \models \phi$ / $M \models_X \phi$)?

In the case of a set of elements / assignments it is also required that $T \neq \emptyset$ (resp. $X \neq \emptyset$) since for all our logics it is the case that the empty set satisfies all formulas and hence the question would become trivial if we allowed it here. ┘

The following observation will be useful in Chapter 6.

Remark 2.19. *If ϕ is a formula over the vocabulary τ and*

$$\psi := \exists R_1 \dots \exists R_n \exists f_1 \dots \exists f_m \phi$$

with $R_1, \dots, R_n, f_1, \dots, f_m \in \tau$, then ϕ is satisfiable iff the second-order formula ψ is satisfiable.

2.4.2 MODEL CHECKING

The next problem is the model checking of a given structure for a given formula, i. e. deciding whether a given structure satisfies a given formula. This question for example arises in system verification – where it shall be checked if an already designed system does or does not have some specific properties.

Definition 2.20. Let $\mathcal{L}$ be a logic and its semantics be defined over a class of structures $\mathcal{C}$. Then its *model checking problem* is defined as

Problem: $\mathcal{L}$-$\mathcal{C}$-MC

Input: A formula $\phi \in \mathcal{L}$ and a structure $\mathfrak{A} \in \mathcal{C}$.
Question: Does $\mathfrak{A}$ satisfy ϕ, i. e. $\mathfrak{A} \models \phi$?

Again, if $\mathcal{C}$ is clear from the context we leave it out. Also, as above, it may sometimes be necessary to not only have a structure but also one or more elements from the structure. In this case these elements are part of the input, i. e. they have to be given together with the structure when the question is asked. ⌟

2.4.3 EXPRESSIVENESS

The last of our problems is *expressiveness*. This makes most sense in comparing two logics $\mathcal{L}$ and $\mathcal{L}'$. In this case the question is whether every property definable in one logic is also definable in the other. More formally we have the following definitions.

Definition 2.21. Let ϕ and ψ be two formulas with their semantics defined over the class of structures $\mathcal{C}$. We say that ψ is a *logical consequence* of ϕ, in symbols $\phi \Rrightarrow \psi$, iff for all structures $\mathfrak{A} \in \mathcal{C}$ it holds that

$$\mathfrak{A} \models \phi \quad \text{implies} \quad \mathfrak{A} \models \psi.$$

We say that ϕ and ψ are *logically equivalent* (in $\mathcal{C}$), in symbols $\phi \Longleftrightarrow \psi$, iff $\phi \Rrightarrow \psi$ and $\phi \Lleftarrow \psi$. ⌟

Definition 2.22. Let $\mathcal{L}$ and $\mathcal{L}'$ be two logics with their semantics defined over the classes of structures $\mathcal{C}$ and $\mathcal{C}'$ with $\mathcal{C} \subseteq \mathcal{C}'$. Then we say that $\mathcal{L}$ is *reducible* to $\mathcal{L}'$ ($\mathcal{L} \leqq \mathcal{L}'$) iff for all formulas $\phi \in \mathcal{L}$ there is a formula $\psi \in \mathcal{L}'$ such that $\phi \Longleftrightarrow \psi$ (in $\mathcal{C}$) holds.

We say that $\mathcal{L}$ and $\mathcal{L}'$ are *equivalent* ($\mathcal{L} \equiv \mathcal{L}'$) iff $\mathcal{L} \leqq \mathcal{L}'$ and $\mathcal{L}' \leqq \mathcal{L}$ hold. And we write $\mathcal{L} < \mathcal{L}'$ iff both $\mathcal{L} \leqq \mathcal{L}'$ and $\mathcal{L}' \nleqq \mathcal{L}$ hold. ⌟

For extensions of first-order logic we usually restrict our attention to sentences when dealing with expressiveness, e. g. $\mathcal{FO}$ only means the set of first-order sentences in this context and not the set of all first-order formulas.

One could think that showing equivalence of two logics $\mathcal{L}$ and $\mathcal{L}'$ would also show that their model-checking and satisfiability problems are of the same complexity. Unfortunately, this is not always the case, i. e. it is possible that $\mathcal{L} \equiv \mathcal{L}'$ but $\mathcal{L}$-SAT $\not\equiv_{\mathrm{m}}^{\mathrm{P}}$ $\mathcal{L}'$-SAT and/or $\mathcal{L}$-MC $\not\equiv_{\mathrm{m}}^{\mathrm{P}}$ $\mathcal{L}'$-MC. This is caused by a possible blow-up in translating from one logic to the other.

Dashed lines mark "$\subseteq$" inclusions and solid lines mark "$\subsetneq$" inclusions.

CHAPTER 3

DEPENDENCE LOGIC

3.1 FIRST-ORDER DEPENDENCE LOGIC

In this thesis, the semantics of $\mathcal{D}$ and $\mathcal{IF}$ are both based on the concept of teams. For $\mathcal{IF}$, we follow the exposition of [CDJ09] and the recent monograph [MSS11].

Definition 3.1 (Syntax of $\mathcal{IF}$). The syntax of $\mathcal{IF}$ extends the syntax of $\mathcal{FO}$ by the rules

$$\phi \ ::= \ \exists x/W\,\phi \ \mid \ \forall x/W\,\phi,$$

where x is a first-order variable and W a finite set of first-order variables. The quantifiers are called *slashed quantifiers* in this case. ⌟

Definition 3.2 (Syntax of $\mathcal{D}$, [Vää07]). The syntax of $\mathcal{D}$ extends the syntax of $\mathcal{FO}$ by the rules

$$\phi \quad ::= \quad =\!(t_1,\dots,t_n) \ \mid \ \neg{=}(t_1,\dots,t_n) \ \mid \ \phi \varovee \phi,$$

where $t_1,\dots,t_n$ are terms. An atomic formula of the form $=\!(t_1,\dots,t_n)$ is called *dependence atom* and in this thesis the terms t_i will mostly be plain variables.

The *arity* of a dependence atom $=\!(x_1,\dots,x_{n-1},x_n)$ is defined as $n-1$, i. e. the arity of a dependence atom is the arity of the determinating function whose existence it asserts.

In the following chapters we usually denote by $\mathcal{D}$ the above logic but without the $\varovee$ operator. The version that includes $\varovee$ is primarily used for the translations in Definition 3.11. ⌟

Note that we could have defined negation to be arbitrary and not only atomic. A sentence that is not in negation normal form could then be evaluated by first pushing the negations down to the atomic level by using de Morgan's law and other well-known rules. However, as we will see in Section 3.1.1, non-atomic negation would be purely syntactical and not semantical (*semantical* meaning that $\neg\phi$ is satisfied iff ϕ is not satisfied) – whereas for plain first-order logic the syntactical and semantical notions coincide.

For a set $W \subseteq \mathrm{dom}(X)$ we call F *W-independent* (resp. *W-determined*) if for all $s, s' \in X$ with $s(x) = s'(x)$ for all $x \in \mathrm{dom}(X) \backslash W$ (resp. for all $x \in W$) we have that $F(s) = F(s')$.

Definition 3.3 (Semantics of $\mathcal{D}$ and $\mathcal{IF}$, [Hod97a, Vää07]). Let $\mathfrak{A}$ be a model and X a team of A. For $\mathcal{IF}$ the satisfaction relation $\mathfrak{A} \models_X \phi$ from Definition 2.2 is extended by the rules

- $\mathfrak{A} \models_X \exists x/W\phi$ iff $\mathfrak{A} \models_{X(F/x)} \phi$ for some W-independent function $F\colon X \to A$,
- $\mathfrak{A} \models_X \forall x/W\phi$ iff $\mathfrak{A} \models_{X(A/x)} \phi$

and for $\mathcal{D}$ by the rules

- $\mathfrak{A} \models_X =\!(t_1, \ldots, t_n)$ iff for all $s, s' \in X$ such that $t_1^{\mathfrak{A}}\langle s\rangle = t_1^{\mathfrak{A}}\langle s'\rangle$, $\ldots, t_{n-1}^{\mathfrak{A}}\langle s\rangle = t_{n-1}^{\mathfrak{A}}\langle s'\rangle$ it holds that $t_n^{\mathfrak{A}}\langle s\rangle = t_n^{\mathfrak{A}}\langle s'\rangle$,
- $\mathfrak{A} \models_X \neg\!=\!(t_1, \ldots, t_n)$ iff $X = \emptyset$,
- $\mathfrak{A} \models_X \phi \otimes \psi$ iff $\mathfrak{A} \models_X \phi$ or $\mathfrak{A} \models_X \psi$.

Above, we assume that the domain of X contains $\mathrm{Fr}(\phi)$. Finally, a sentence ϕ is true in a model $\mathfrak{A}$ ($\mathfrak{A} \models \phi$) if $\mathfrak{A} \models_{\{\emptyset\}} \phi$. ⌟

Note the seemingly rather strange semantics of negated dependence atoms. The rationale for this, given by Väänänen [Vää07, p. 24], is the fact that if we negate dependence atoms and maintain the same duality as between positive and negative first-order literals (cf. Definition 2.2) we get the condition

$$\begin{aligned} \forall s, s' \in X\colon t_1^{\mathfrak{A}}\langle s\rangle = t_1^{\mathfrak{A}}\langle s'\rangle, \ldots, t_{n-1}^{\mathfrak{A}}\langle s\rangle = t_{n-1}^{\mathfrak{A}}\langle s'\rangle \\ \text{and} \quad t_n^{\mathfrak{A}}\langle s\rangle \neq t_n^{\mathfrak{A}}\langle s'\rangle \end{aligned}$$

and this is only true if $X = \emptyset$.

Above, we denote *dependence disjunction* instead of *classical disjunction* with $\vee$ because the semantics of dependence disjunction is an extension of the semantics of usual first-order disjunction and thus we preserve downward compatibility of our notation in this way. However, we still call the $\otimes$ operator “classical” because in a higher level context – where our sets of states are viewed as single objects themselves – it is indeed the usual disjunction, cf. [AV09]. Note that

$$\phi \otimes \psi \quad \Rrightarrow \quad \phi \vee \psi$$

holds but not the other way around.

3.1.1 BASIC PROPERTIES OF $\mathcal{D}$ AND $\mathcal{IF}$

Now we will state some basic properties of $\mathcal{D}$ and $\mathcal{IF}$.

First we will see that the game theoretically motivated negation $\neg$ of $\mathcal{D}$ and $\mathcal{IF}$ does not satisfy the *law of excluded middle* and is therefore not the classical Boolean negation.

Proposition 3.4 (Law of excluded middle failure). *Let* $\phi := {=}(x)$, $\mathfrak{A}$ *a structure with universe* $A := \{a, b\}$ *and* $X := \{\{x \mapsto a\}, \{x \mapsto b\}\}$. *Then* $\mathfrak{A} \not\models \phi$ *and* $\mathfrak{A} \not\models \neg\phi$.

Also, many familiar propositional equivalences of connectives do not hold in $\mathcal{D}$ and $\mathcal{IF}$. For example, the idempotence of disjunction fails, which can be used to show that the distributivity laws of disjunction and conjunction do not hold either. We refer the interested reader to [Vää07, Section 3.3] for a detailed exposition on propositional equivalences of connectives in $\mathcal{D}$ (and also $\mathcal{IF}$).

The following fact is a fundamental property of all formulas of $\mathcal{D}$ and $\mathcal{IF}$.

Proposition 3.5 (Downward closure property, [Vää07, Hod97a]). *Let* ϕ *be a formula of* $\mathcal{D}$ *or* $\mathcal{IF}$, $\mathfrak{A}$ *a model, and* $Y \subseteq X$ *teams. Then* $\mathfrak{A} \models_X \phi$ *implies* $\mathfrak{A} \models_Y \phi$.

As argued in [Vää07, Proposition 3.10], the downward closure property suits the intuition that a true formula expressing dependence should not become false when making the team smaller, since if dependence holds in a large set then it does even more in a smaller set.

A feature of $\mathcal{D}$ and $\mathcal{IF}$ that nicely accomodates the downward closure is that $\mathfrak{A} \models_{\emptyset} \phi$ holds for all $\mathfrak{A}$ and all formulas ϕ of $\mathcal{D}$ and $\mathcal{IF}$. This observation is important in noting that for *sentences* ϕ and ψ it holds that

$$\phi \vee \psi \Longleftrightarrow \phi \otimes \psi.$$

Väänänen [Vää07, Chapter 6.1] and Hodges [Hod97b] have shown that the expressive power of sentences of $\mathcal{D}$ and $\mathcal{IF}$ coincides with that of existential second-order sentences:

Theorem 3.6. $\mathcal{D} \equiv \mathcal{IF} \equiv \mathcal{ESO}$.

Let X be a team with domain $\{x_1, \dots, x_k\}$ and $V \subseteq \{x_1, \dots, x_k\}$. We denote by $X \upharpoonright V$ the team $\{s \upharpoonright V \mid s \in X\}$ with domain V (here, $s \upharpoonright V$ denotes the restriction of the function s to the domain V). The following proposition shows that the truth of a $\mathcal{D}$-formula only depends on the interpretations of the variables occurring free in the formula.

Proposition 3.7 ([Vää07, CDJ09]). *Let $\phi \in \mathcal{D}$ be any formula or $\phi \in \mathcal{IF}$ a sentence. If $V \supseteq \mathrm{Fr}(\phi)$, then $\mathfrak{A} \models_X \phi$ if and only if $\mathfrak{A} \models_{X \upharpoonright V} \phi$.*

The analogue of Proposition 3.7 does not hold for open formulas of $\mathcal{IF}$. In other words, the truth of an $\mathcal{IF}$-formula may depend on the interpretations of variables that do not occur in the formula. For example, the truth of the formula

$$\phi := \exists x/\{y\}(x = y)$$

in a team X with domain $\{x, y, z\}$ depends on the values of z in X, although z does not occur in ϕ.

We have noted in the last chapter that for first-order formulas the usual single-assignment based semantics coincides with our team semantics, cf. Remark 2.3. This is not always the case for $\mathcal{D}$ and $\mathcal{IF}$ formulas.

Definition 3.8 (Flatness). Let ϕ be a $\mathcal{D}$ or an $\mathcal{IF}$ formula. Then ϕ is said to be *flat* iff for all structures $\mathfrak{A}$ and teams X of A it holds that

$$\mathfrak{A} \models_X \phi \quad \text{iff} \quad \forall s \in X,\ \mathfrak{A} \models_{\{s\}} \phi.$$

⌟

The left-to-right implication in the above definition follows from the downward closure property (Proposition 3.5) while the other direction does not always hold. For plain first-order formulas, however, it does.

3.1.2 TWO-VARIABLE DEPENDENCE LOGIC

Definition 3.9 ($\mathcal{D}^k$, $\mathcal{IF}^k$). $\mathcal{D}^k$ and $\mathcal{IF}^k$ are defined as restrictions of $\mathcal{D}$ and $\mathcal{IF}$ analogous to the definition of $\mathcal{FO}^k$ from $\mathcal{FO}$ (Definition 2.6). ⌟

3.2 MODAL DEPENDENCE LOGIC

Now we will introduce the syntax and semantics of modal dependence logic and show some important properties of it. For a more profound overview consult Väänänen's introduction [Vää08].

Definition 3.10 (Syntax of $\mathcal{MDL}$). The syntax of $\mathcal{MDL}$ extends the syntax of modal logic by the rules

$$\phi ::= \,=\!(p_1, \ldots, p_{n-1}, p_n) \mid \neg{=}(p_1, \ldots, p_{n-1}, p_n) \mid \phi \varovee \phi,$$

where $n \geqslant 1$. ⌟

The semantics of $\mathcal{MDL}$ will be given by a translation to $\mathcal{D}^2$. In the first-order side of the translation we do not use the usual dependence atoms but instead a variation of them. This is, however, not a problem since the variation turns out to be definable by the usual version. We follow this approach because it nicely demonstrates that the embedding of modal logic into two-variable first-order logic carries over to the respective dependence logics.

Definition 3.11 (Semantics of $\mathcal{MDL}$). We extend the translation from $\mathcal{ML}$ to $\mathcal{FO}^2$ (Definition 2.10) by the following rules to get a translation from $\mathcal{MDL}$ to $\mathcal{D}^2$:

$$\begin{aligned} =\!(p_1, \ldots, p_n) &\mapsto\ =\!(P_1(x), \ldots, P_n(x)), \\ \neg{=}(p_1, \ldots, p_n) &\mapsto \bot, \\ \phi \varovee \psi &\mapsto \widetilde{\phi}(x) \varovee \widetilde{\psi}(x). \end{aligned}$$

⌟

As stated above the resulting formula is not a strict $\mathcal{D}$ formula since inside the dependence atoms there are atomic formulas instead of terms. We can, however, further translate the formula by the rule

$$=\!(P_1(x), \ldots, P_n(x)) \mapsto \exists y_1 \ldots \exists y_n \Big(\bigwedge_{i=1}^{n} (y_i = c \leftrightarrow P_i(x)) \wedge\ =\!(y_1, \ldots, y_n) \Big),$$

where c is either a constant symbol from the first-order vocabulary or a variable that is existentially quantified in the beginning of the complete formula, i. e. its value is the same in all subformulas.

In Chapter 4 we will investigate and classify several fragments of $\mathcal{MDL}$.

Definition 3.12 ($\mathcal{MDL}_k$). $\mathcal{MDL}_k$ is the subset of $\mathcal{MDL}$ that contains all formulas which do not contain any dependence atoms whose arity is greater than k. ⌟

We will classify $\mathcal{MDL}$ for all fragments defined by sets of operators.

Definition 3.13 ($\mathcal{MDL}(M)$, $\mathcal{PDL}$). Let $\mathcal{L}$ be a modal logic and let M be a set of operators and constants from the language of $\mathcal{L}$. Then $\mathcal{L}(M)$ is the subset of $\mathcal{L}$ containing all formulas built from atomic propositions using only operators and constants from M. We usually write $\mathcal{L}(op_1, op_2, \ldots)$ instead of $\mathcal{L}(\{op_1, op_2, \ldots\})$.

Now, $\mathcal{PDL}$ is defined as $\mathcal{MDL}(\wedge, \vee, \neg, =)$, i. e. the restriction of $\mathcal{MDL}$ to formulas without modalities and without classical disjunction $\varovee$. ⌟

3.2.1 BASIC PROPERTIES OF $\mathcal{MDL}$

Most properties of first-order dependence logic carry over to modal dependence logic, e. g. neither having the law of excluded middle (Proposition 3.4) nor the idempotence of disjunction or the fact that the empty team satisfies all formulas.

Furthermore, the downward closure property (Proposition 3.5) holds for modal dependence logic as well.

Proposition 3.14 (Downward closure property, [Vää08]). *Let $K = (S, R, \pi)$ be a Kripke structure, $T' \subseteq T \subseteq S$ and $\phi \in \mathcal{MDL}$. Then $W, T \models \phi$ implies $W, T' \models \phi$.*

Also, the concept of flatness can be translated to modal logic in the canonical way.

Definition 3.15 (Flatness). An $\mathcal{MIDL}$ formula ϕ is said to be *flat* if for any Kripke model K and any team T of K

$$K, T \models \phi \quad \text{iff} \quad \forall s \in T,\ K, \{s\} \models \phi.$$

⌟

And again, analogous to first-order logic, all plain modal logic formulas are flat.

Additionally, some more equivalences follow almost immediately from the semantics of $\mathcal{MDL}$.

Lemma 3.16. *The following holds for $\mathcal{MDL}$:*

a) $\top \Longleftrightarrow p \vee \neg p, \quad \bot \Longleftrightarrow p \wedge \neg p \Longleftrightarrow \neg{=}(p_1, \ldots, p_n)$,

b) ${=}(p) \Longleftrightarrow p \varovee \neg p$ *and*

c) $${=}(p_1, \ldots, p_n) \Longleftrightarrow \bigvee_{i_1, \ldots, i_{n-1} \in \{\top, \bot\}} \left(p_1^{i_1} \wedge \ldots \wedge p_{n-1}^{i_{n-1}} \wedge (p_n \varovee \neg p_n)\right),$$

where $p^\top := p$ and $p^\bot := \neg p$.

PROOF. The only difficult case is (c). For this note that $K, T \models {=}(p_1, \ldots, p_n)$ means that for all subteams $T' \subseteq T$ where the evaluations of $p_1, \ldots, p_{n-1}$ are each constant in T', it holds that the value of p_n is also constant in T'. On the other hand, the right hand side of the equivalence is true in a team T if and only if T can be partitioned into 2^{n-1} subteams T'' such that in each team T'' the evaluations of $p_1, \ldots, p_{n-1}$ are as specified and the value of p_n is constant. Since all possible evaluations of $p_1, \ldots, p_{n-1}$ occur in the disjunction all the subteams T' from above will occur as one of the teams T'' and vice versa. ■

Note that the first-order equivalents of (b) and (c) do not hold – contrary to (a). Here, the crucial difference between first-order and modal logic is that in the latter case variables are always only Boolean; that especially means that the set of possible values for a variable occuring in a dependence atom is finite and fixed.

3.3 INTUITIONISTIC DEPENDENCE LOGIC

Intuitionistic dependence logic was introduced in [AV09].

Definition 3.17 ($\mathcal{IDL}$). The syntax of $\mathcal{IDL}$ extends the syntax of $\mathcal{D}$ by the rule

$$\phi \ ::= \ \phi \rightarrow \phi.$$

Here, → denotes *intuitionistic implication*.

For $\mathcal{IDL}$ the satisfaction relation from Definition 3.3 is extended by the rule

$$\mathfrak{A} \models_X \phi \rightarrow \psi \text{ iff for all } Y \subseteq X \text{ with } \mathfrak{A} \models_Y \phi \text{ it holds that } \mathfrak{A} \models_Y \psi,$$

i. e. $\phi \rightarrow \psi$ is satisfied in a team iff truth of ϕ in a subteam always implies truth of ψ in that subteam. ⌟

Now we introduce the modal logic version of intuitionistic dependence logic.

Definition 3.18 ($\mathcal{MIDL}$). The syntax of $\mathcal{MIDL}$ extends the syntax of $\mathcal{MDL}$ by the rule

$$\phi \ ::= \ \phi \rightarrow \phi.$$

The semantics of $\mathcal{MIDL}$ is defined by the extension of the translation from Definition 3.11 by the rule

$$\phi \rightarrow \psi \quad \mapsto \quad \widetilde{\phi}(x) \rightarrow \widetilde{\psi}(x).$$

⌟

All the properties of $\mathcal{MDL}$ from Section 3.2.1 hold for $\mathcal{MIDL}$ as well. In addition, some more equivalences hold.

Lemma 3.19. *All equivalences from Lemma 3.16 hold for $\mathcal{MIDL}$ and also the following:*

a) $\neg p \iff p \rightarrow \bot$,

b) $=\!(p_1, \ldots, p_n) \iff \big(=\!(p_1) \wedge \ldots \wedge =\!(p_{n-1})\big) \rightarrow =\!(p_n)$ *and*

c) $\phi \rightarrow \psi \;\equiv\; \phi^{\mathrm{d}} \vee \psi$ *if both ϕ and ψ are $\mathcal{ML}$ formulas and ϕ^{d} is the dual of ϕ (cf. Definition 2.9), i. e. $\rightarrow$ has a conservative semantics – in the sense that for $\mathcal{ML}$ formulas its semantics coincides with the semantics of the usual classical modal logic implication.*

Note that although $\neg p$ is equivalent to $p \rightarrow \bot$, of course one of $\neg$ or $\bot$ is needed to achieve full $\mathcal{MIDL}$ expressiveness. The above lemma also shows that we could have equivalently defined the syntax of $\mathcal{MIDL}$ without dependence atoms. The rationale for making the constants, the $\neg$ operator and the $=\!(\cdot)$ operator parts of the language, although we could have left out some of them by applying Lemma 3.19, is that we will investigate sublogics of $\mathcal{MIDL}$ where we will still use constants and negation but not always $\wedge$, $\vee$ and $\rightarrow$.

Finally, we define the propositional version of intuitionistic dependence logic.

Definition 3.20 ($\mathcal{PIDL}$). $\mathcal{PIDL}$ is defined as

$$\mathcal{MIDL}(\wedge, \varovee, \neg, \rightarrow, =).$$

$\lrcorner$

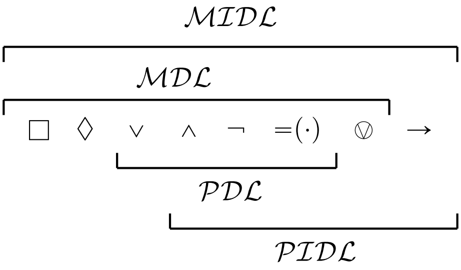
From Lemma 3.19 we obtain the following characterizations:

$$\begin{aligned}
\mathcal{PIDL} \;&\equiv\; \mathcal{MIDL}(\wedge, \varovee, \neg, \rightarrow) \\
&\equiv\; \mathcal{MIDL}(\wedge, \varovee, \bot, \rightarrow) \quad \text{and} \\
\mathcal{MIDL} \;&\equiv\; \mathcal{MIDL}(\Box, \Diamond, \wedge, \vee, \varovee, \neg, \rightarrow) \\
&\equiv\; \mathcal{MIDL}(\Box, \Diamond, \wedge, \vee, \varovee, \bot, \rightarrow).
\end{aligned}$$

Note that $\mathcal{PDL} \nsubseteq \mathcal{PIDL}$ since $\mathcal{PDL}$ uses dependence disjunction and $\mathcal{PIDL}$ uses classical disjunction.

Figure 3.1 shows the main modal logics considered in this thesis.

In later chapters we will investigate the model checking and satisfiability problems of several dependence logics. For now we note that, as pointed out in Section 2.4.3, the above equivalences between $\mathcal{MIDL}$ fragments do not necessarily imply that the computational complexity of the problems is the same



$\mathcal{MIDL}$
$\mathcal{MDL}$
$\Box$ $\Diamond$ $\vee$ $\wedge$ $\neg$ $=(\cdot)$ $\ovee$ $\rightarrow$
$\mathcal{PDL}$
$\mathcal{PIDL}$

Figure 3.1: Sublogics of $\mathcal{MIDL}$

for equivalent fragments, i. e. it is possible to have sets $M \neq M'$ of operators such that $\mathcal{MIDL}(M) \equiv \mathcal{MIDL}(M')$ but $\mathcal{MIDL}(M)$-MC $\not\equiv^{\mathrm{P}}_{\mathrm{m}}$ $\mathcal{MIDL}(M')$-MC. This is caused by a possible exponential blow-up in translating from one fragment to another.

CHAPTER 4

MODAL DEPENDENCE LOGIC

4.1 SATISFIABILITY

In this section we will classify operator fragments of $\mathcal{MDL}$ according to the complexity of their satisfiability problem, i. e. – according to Definition 2.18 – for all $M \subseteq \{\Box, \Diamond, \wedge, \vee, \varovee, \neg, =\}$ and all $k \geqslant 0$ the problem

Problem: $\mathcal{MDL}(M)$-SAT ($\mathcal{MDL}_k(M)$-SAT)
Input: A $\mathcal{MDL}(M)$ (resp. $\mathcal{MDL}_k(M)$) formula ϕ.
Question: Is there a Kripke structure W and a non-empty set T of worlds in W such that $W, T \models \phi$ holds?

Note that, because of the downward closure property (Proposition 3.14), to check satisfiability of a formula ϕ it is enough to check whether there is a frame W and a single world w in W such that $W, \{w\} \models \phi$.

Our first lemma concerns sets of operators including classical disjunction.

Lemma 4.1. *Let M be a set of $\mathcal{MDL}$ operators. Then the following hold:*

a) Every $\mathcal{MDL}(M \cup \{\varovee\})$ ($\mathcal{MDL}_k(M \cup \{\varovee\})$) formula ϕ is equivalent to a formula

$$\bigovee_{i=1}^{2^{|\phi|}} \psi_i$$

with $\psi_i \in \mathcal{MDL}(M)$ (resp. $\mathcal{MDL}_k(M)$) for all $i \in \{1, \ldots, 2^{|\phi|}\}$.

b) If $\mathcal{C}$ is an arbitrary complexity class with $\mathsf{P} \subseteq \mathcal{C}$ and $\mathcal{MDL}(M)$-SAT $\in \mathcal{C}$ ($\mathcal{MDL}_k(M)$-SAT $\in \mathcal{C}$) then $\mathcal{MDL}(M \cup \{\varovee\})$-SAT $\in \exists{\cdot}\mathcal{C}$ (resp. $\mathcal{MDL}_k(M \cup \{\varovee\})$-SAT $\in \exists{\cdot}\mathcal{C}$).

Proof. a) follows from the distributivity of $\varovee$ with all other $\mathcal{MDL}$ operators. More specifically, $\phi \star (\psi \varovee \sigma) \Longleftrightarrow (\phi \star \psi) \varovee (\phi \star \sigma)$ for $\star \in \{\wedge, \vee\}$ and $\nabla(\phi \varovee \psi) \Longleftrightarrow (\nabla\phi) \varovee (\nabla\phi)$ for $\nabla \in \{\Diamond, \Box\}$.[1] b) follows from a) with the observation that $\bigovee_{i=1}^{2^{|\phi|}} \psi_i$ is satisfiable if and only if there is an $i \in \{1, \dots, 2^{|\phi|}\}$ such that ψ_i is satisfiable. Note that given $i \in \{1, \dots, 2^{|\phi|}\}$ the formula ψ_i can be computed from the original formula ϕ in polynomial time by choosing (for all $j \in \{1, \dots, |\phi|\}$) from the jth subformula of the form $\psi \varovee \sigma$ the formula ψ if the jth bit of i is 0 and σ if it is 1. ■

We need the following simple property of monotone $\mathcal{MDL}$ formulas.

Lemma 4.2. *Let M be a set of $\mathcal{MDL}$ operators with $\neg \notin M$. Then an arbitrary $\mathcal{MDL}(M)$ formula ϕ is satisfiable iff the formula generated from ϕ by replacing every dependence atom and every atomic proposition with the same fresh atomic proposition t is satisfiable.*

Proof. If a frame W is a model for ϕ, so is the frame generated from W by setting all atomic propositions in all worlds to true. ■

We are now able to classify some cases that can be easily reduced to known results.

Corollary 4.3.

a) If $\{\Box, \Diamond, \wedge, \vee, \neg\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \vee, \neg, \top, \bot, \varovee\}$ then $\mathcal{MDL}(M)$-Sat is PSPACE*-complete.*

b) If $\{\Box, \Diamond, \wedge, \vee, \bot\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \vee, \top, \bot, =, \varovee\}$ then $\mathcal{MDL}(M)$-Sat and $\mathcal{MDL}_k(M)$-Sat are PSPACE*-complete for all $k \geqslant 0$.*

c) If $\{\Box, \Diamond, \wedge, \bot\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \top, \bot, =\}$ then $\mathcal{MDL}(M)$-Sat and $\mathcal{MDL}_k(M)$-Sat are coNP*-complete for all $k \geqslant 0$.*

d) If $M \subseteq \{\Box, \Diamond, \wedge, \vee, \top, =, \varovee\}$ then every $\mathcal{MDL}(M)$ formula is satisfiable.

e) If $M \subseteq \{\wedge, \neg, \top, \bot, =\}$ then $\mathcal{MDL}(M)$-Sat is in P.

f) If $M \subseteq \{\wedge, \vee, \top, \bot, =, \varovee\}$ then $\mathcal{MDL}(M)$-Sat is in P.

Proof. The lower bound of a) was shown by Ladner [Lad77], who proves PSPACE-completeness for the case of full ordinary modal logic. The upper bound follows from this, Lemma 4.1 and the fact that $\exists\cdot$PSPACE = PSPACE.

---

[1] Interestingly, but not of relevance for our work, $\phi \varovee (\psi \vee \sigma) \not\Longleftrightarrow (\phi \varovee \psi) \vee (\phi \varovee \sigma)$.

The lower bound for b) was shown by Hemaspaandra [Hem01, Theorem 6.5] and the upper bound follows from a) together with Lemma 4.2.

The lower bound for c) was shown by Donini et al. [DLN$^+$92] who prove NP-hardness of the problem to decide whether an $\mathcal{ALE}$-concept is unsatisfiable. $\mathcal{ALE}$ is a description logic which essentially is nothing else than $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg, \top, \bot)$ ($\neg$ is not used in the hardness proof and $\top$, although it is used in the original proof, can be substituted by a fresh atomic proposition t). For the upper bound Ladner's PSPACE-algorithm [Lad77] can be used, as in the case without disjunction it is in fact a coNP-algorithm, together with Lemma 4.2.

d) follows from Lemma 4.2 together with the fact that every $\mathcal{MDL}$ formula with t as the only atomic subformula is satisfied in the transitive singleton, i. e. the frame consisting of only one state which has itself as successor, in which t is true.

e) follows from the polynomial time complexity of deciding satisfiability of a 1CNF formula. Finally, f) reduces to Boolean formula evaluation by Lemma 4.2. Note that for e) and f) dependence atoms can be replaced by $\top$ because there we do not have any modality. ■

4.1.1 POOR MAN'S DEPENDENCE LOGIC

We now turn to the Σ_2^{P}-complete cases. These include monotone poor man's logic, i. e. modal logic without negation and dependence disjunction, with and without dependence atoms.

Theorem 4.4. *If* $\{\Box, \Diamond, \wedge, \neg, \varovee\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \neg, \top, \bot, \varovee\}$ *or* $\{\Box, \Diamond, \wedge, \bot, \varovee\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \top, \bot, =, \varovee\}$ *then* $\mathcal{MDL}(M)$-SAT *and* $\mathcal{MDL}_k(M)$-SAT *are* Σ_2^{P}*-complete for all* $k \geqslant 0$.

PROOF. Proving the upper bound for the second case reduces to proving the upper bound for the first case by Lemma 4.2. For the first case it holds with Lemma 4.1 that $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg, \top, \bot, \varovee)$-SAT $\in \exists\cdot\mathsf{coNP} = \Sigma_2^{\mathsf{P}}$ since $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg, \top, \bot)$-SAT $\in$ coNP (cf. the proof of Corollary 4.3c). The latter follows directly from Ladner's PSPACE-algorithm for modal logic satisfiability [Lad77] which is in fact a coNP-algorithm in the case without disjunction.

For the lower bound we consider the quantified constraint satisfaction problem $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ shown to be Π_2^{P}-complete by Bauland et al. [BBC$^+$10]. This problem can be reduced to the complement of $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg/\bot, \varovee)$-SAT in polynomial time.

An instance of $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ consists of universally quantified Boolean variables $p_1, \ldots, p_k$, existentially quantified Boolean variables $p_{k+1}, \ldots, p_n$ and a set of clauses each consisting of exactly three of those variables. $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ is the set of all those instances for which for every truth assignment for $p_1, \dots, p_k$ there is a truth assignment for $p_{k+1}, \dots, p_n$ such that in each clause exactly one variable evaluates to true. Note that for our reduction it is necessary that in each clause the variables are pairwise different whereas in $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ this does not need to be the case. However, the Π_2^{P}-hardness proof can be adapted to account for this as follows.

Claim 1. $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ *with pairwise different variables in each clause is* Π_2^{P}*-hard.*

PROOF OF CLAIM 1. We give a reduction from $\text{3CNF-}\overline{\mathrm{QBF}_2}$, which is long known to be Π_2^{P}-complete (cf. [Wra77]). The only differences between an instance of $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ and an instance of $\text{3CNF-}\overline{\mathrm{QBF}_2}$ are that in the latter a clause may contain negated variables, more than one literal that evaluates to true and the same variable more than once.

Our reduction works as follows. The quantification of all original variables stays unchanged. All newly introduced variables are existentially quantified. Our new set of clauses consists of the clauses

a) $\{t, f, f'\}, \{t, f', f''\}, \{t, f'', f\}$, where t, f, f', f'' are new variables,

b) for each original variable x: $\{x, x', f\}$ and

c) for each original clause $\{x, y, z\}$: $\{f, \hat{x}, a\}, \{a', \hat{y}, b\}, \{b', \hat{z}, f\}$, $\{a, a', a''\}, \{b, b', b''\}$,
where a, a', a'', b, b', b'' are new variables (fresh for each original clause) and $\hat{u} := \begin{cases} p & \text{if } u = p \\ p' & \text{if } u = \neg p \end{cases}$.

a) enforces the new variable f to evaluate to $\bot$ and b) simulates negated variables. c) uses $\mathrm{R}_{1/3}$-clauses to allow for more than one of the three literals x, y and z to be true by splitting one old clause in three new clauses. But at the same time it still ensures that at least one of them is true by making the new variables interdependent in such a way that at most two of them can be true. $\blacktriangleleft$

For the reduction from $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ to the complement of $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg/\bot, \varovee)$-SAT we extend a technique from the coNP-hardness proof for $\mathcal{MDL}(\Box, \Diamond, \wedge, \bot)$-SAT by Donini et al. [DLN+92, Theorem 3.3]. Let $p_1, \dots, p_k$ be the universally quantified and $p_{k+1}, \dots, p_n$ the existentially quantified variables of a $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ instance and let $C_1, \dots, C_m$ be its clauses (we assume w.l.o.g. that each variable occurs in at least one clause). Then the corresponding $\mathcal{MDL}(\Box, \Diamond, \wedge, \bot, \varovee)$ formula is

$$\begin{array}{llllllll}
\phi := & \displaystyle\bigwedge_{i=1}^{k} & (& \nabla_{i1} \ldots \nabla_{im} & \nabla_{i1} \ldots \nabla_{im} & \Box^{i-1}\Diamond\Box^{k-i} & p & \\
 & & \varovee & \Box^{m} & \Box^{m} & \Box^{i-1}\Diamond\Box^{k-i} & p &) \\
 & \wedge \quad \displaystyle\bigwedge_{i=k+1}^{n} & & \nabla_{i1} \ldots \nabla_{im} & \nabla_{i1} \ldots \nabla_{im} & \Box^{k} & p & \\
 & \wedge & & \Box^{m} & \Box^{m} & \Box^{k} & \bot &
\end{array}$$

where p is an arbitrary atomic proposition and $\nabla_{ij} := \begin{cases} \Diamond & \text{if } p_i \in C_j \\ \Box & \text{else} \end{cases}$.

For the corresponding $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg, \varovee)$ formula replace every $\bot$ with $\neg p$.

To prove the correctness of our reduction we will need two claims.

Claim 2. *For $r, s \geqslant 0$ a $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg, \top, \bot)$ formula $\Diamond\phi_1 \wedge \ldots \wedge \Diamond\phi_r \wedge \Box\psi_1 \wedge \ldots \wedge \Box\psi_s$ is unsatisfiable iff there is an $i \in \{1, \ldots, r\}$ such that $\phi_i \wedge \psi_1 \wedge \ldots \wedge \psi_s$ is unsatisfiable.*

PROOF OF CLAIM 2. "$\Leftarrow$": If $\phi_i \wedge \psi_1 \wedge \ldots \wedge \psi_s$ is unsatisfiable, so is $\Diamond\phi_i \wedge \Box\psi_1 \wedge \ldots \wedge \Box\psi_s$ and even more $\Diamond\phi_1 \wedge \ldots \wedge \Diamond\phi_r \wedge \Box\psi_1 \wedge \ldots \wedge \Box\psi_s$.

"$\Rightarrow$": Suppose that $\phi_i \wedge \psi_1 \wedge \ldots \wedge \psi_s$ is satisfiable for all $i \in \{1, \ldots, r\}$. Then $\Diamond\phi_1 \wedge \ldots \wedge \Diamond\phi_r \wedge \Box\psi_1 \wedge \ldots \wedge \Box\psi_s$ is satisfiable in a frame that consists of a root state and for each $i \in \{1, \ldots, r\}$ a separate branch, reachable from the root in one step, which satisfies $\phi_i \wedge \psi_1 \wedge \ldots \wedge \psi_s$. ◂

Note that $\Diamond\phi_1 \wedge \ldots \wedge \Diamond\phi_r \wedge \Box\psi_1 \wedge \ldots \wedge \Box\psi_s$ is always satisfiable if $r = 0$.

Definition. Let $v\colon \{p_1, \ldots, p_k\} \to \{0, 1\}$ be a valuation of $\{p_1, \ldots, p_k\}$. Then ϕ_v denotes the $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg/\bot)$ formula

$$\begin{array}{llllll}
 & \displaystyle\bigwedge_{\substack{i \in \{1,\ldots,k\},\\ v(p_i)=1}} & \nabla_{i1} \ldots \nabla_{im} & \nabla_{i1} \ldots \nabla_{im} & \Box^{i-1}\Diamond\Box^{k-i} & p \\
\wedge & \displaystyle\bigwedge_{\substack{i \in \{1,\ldots,k\},\\ v(p_i)=0}} & \Box^{m} & \Box^{m} & \Box^{i-1}\Diamond\Box^{k-i} & p \\
\wedge & \displaystyle\bigwedge_{i=k+1}^{n} & \nabla_{i1} \ldots \nabla_{im} & \nabla_{i1} \ldots \nabla_{im} & \Box^{k} & p \\
\wedge & & \Box^{m} & \Box^{m} & \Box^{k} & \neg p \,/\, \bot
\end{array}$$

Claim 3. *Let $v\colon \{p_1,\dots,p_k\} \to \{0,1\}$ be a valuation. Then ϕ_v is unsatisfiable iff v can be continued to a valuation $v'\colon \{p_1,\dots,p_n\} \to \{0,1\}$ such that in each of the clauses $\{C_1,\dots,C_m\}$ exactly one variable evaluates to true under v'.*

PROOF OF CLAIM 3. By iterated use of Claim 2, ϕ_v is unsatisfiable iff there are $i_1,\dots,i_{2m}$ with

$$\begin{array}{rl} i_j \in & \big\{i \in \{1,\dots,n\} \mid \nabla_{ij'} = \Diamond\big\} \setminus \big\{i \in \{1,\dots,k\} \mid v(p_i) = 0\big\} \\ = & \big\{i \in \{1,\dots,n\} \mid p_i \in C_{j'}\big\} \setminus \big\{i \in \{1,\dots,k\} \mid v(p_i) = 0\big\}, \end{array}$$

where $j' := \begin{cases} j & \text{if } j \leqslant m \\ j-m & \text{else} \end{cases}$, such that *(i)*

$$\begin{array}{rlll} \phi_v(i_1,\dots,i_{2m}) := & \bigwedge\limits_{\substack{i\in\{1,\dots,k\},\\ i\in\{i_1,\dots,i_{2m}\},\\ v(p_i)=1}} & \Box^{i-1}\Diamond\Box^{k-i} & p \\ \wedge & \bigwedge\limits_{\substack{i\in\{1,\dots,k\},\\ v(p_i)=0}} & \Box^{i-1}\Diamond\Box^{k-i} & p \\ \wedge & \bigwedge\limits_{\substack{i\in\{k+1,\dots,n\},\\ i\in\{i_1,\dots,i_{2m}\}}} & \Box^{k} & p \\ \wedge & & \Box^{k} & \neg p \,/\, \bot \end{array}$$

is unsatisfiable and such that *(ii)* there are no $a, b \in \{1,\dots,2m\}$ with $a < b$, $\nabla_{i_b a'} = \nabla_{i_b b'} = \Diamond$ (this is the case iff $p_{i_b} \in C_{a'}$ and $p_{i_b} \in C_{b'}$) and $i_a \neq i_b$. Condition *(ii)* simply ensures that no subformula is selected after it has already been discarded in an earlier step. Note that $\phi_v(i_1,\dots,i_{2m})$ is unsatisfiable iff *(i')* for all $i \in \{1,\dots,k\}$: $v(p_i) = 1$ and $i \in \{i_1,\dots,i_{2m}\}$ or $v(p_i) = 0$ (and $i \notin \{i_1,\dots,i_{2m}\}$).

We are now able to prove the claim.

"$\Leftarrow$": For $j = 1,\dots,2m$ choose $i_j \in \{1,\dots,n\}$ such that $p_{i_j} \in C_{j'}$ and $v'(p_{i_j}) = 1$. By assumption, all i_j exist and are uniquely determined. Hence, for all $i \in \{1,\dots,k\}$ we have that $v(p_i) = 0$ (and then $i \notin \{i_1,\dots,i_{2m}\}$) or $v(p_i) = 1$ and there is a j such that $i_j = i$ (because each variable occurs in at least one clause). Therefore condition *(i')* is satisfied. Now suppose there are $a < b$ that violate condition *(ii)*. By definition of i_b it holds that $p_{i_b} \in C_{b'}$ and $v'(p_{i_b}) = 1$. Analogously, $p_{i_a} \in C_{a'}$ and $v'(p_{i_a}) = 1$. By the supposition $p_{i_b} \in C_{a'}$ and $p_{i_a} \neq p_{i_b}$. But since $v'(p_{i_a}) = v'(p_{i_b}) = 1$, that is a contradiction to the fact that in clause $C_{a'}$ only one variable evaluates to true.

"⇒": If ϕ_v is unsatisfiable, there are $i_1, \ldots, i_{2m}$ such that *(i')* and *(ii)* hold. Let the valuation $v' \colon \{p_1, \ldots, p_n\} \to \{0,1\}$ be defined by

$$v'(p_i) := \begin{cases} 1 \text{ if } i \in \{i_1, \ldots, i_{2m}\} \\ 0 \text{ else} \end{cases} .$$

Note that v' is a continuation of v because *(i')* holds.

We will now prove that in each of the clauses $C_1, \ldots, C_m$ exactly one variable evaluates to true under v'. Therefore let $j \in \{1, \ldots, m\}$ be arbitrarily chosen.

By choice of i_j it holds that $p_{i_j} \in C_j$. It follows by definition of v' that $v'(p_{i_j}) = 1$. Hence, there is at least one variable in C_j that evaluates to true.

Now suppose that besides p_{i_j} another variable in C_j evaluates to true. Then by definition of v' it follows that there is a $\ell \in \{1, \ldots, 2m\}$, $\ell \neq j$, such that this other variable is p_{i_ℓ}. We now consider two cases.

Case $j < \ell$: This is a contradiction to *(ii)* since, by definition of ℓ, p_{i_ℓ} is in $C_{j'}$ as well as, by definition of i_ℓ, in $C_{\ell'}$ and $i_j \neq i_\ell$.

Case $\ell < j$: Since $j \in \{1, \ldots, m\}$ it follows that $\ell \leqslant m$. Since $C_{\ell'} = C_{(\ell+m)'}$ it holds that $p_{i_{\ell+m}} \in C_{\ell'}$ and $p_{i_{\ell+m}} \in C_{(\ell+m)'}$. Furthermore $\ell < \ell + m$ and thus, by condition *(ii)*, it must hold that $i_\ell = i_{\ell+m}$. Therefore $p_{i_{\ell+m}} \in C_j$ and $v'(p_{i_{\ell+m}}) = 1$. Because $j < \ell + m$ this is a contradiction to condition *(ii)* as in the first case. ◂

The correctness of the reduction now follows with the observation that ϕ is equivalent to

$$\bigovee_{v \colon \{p_1, \ldots, p_k\} \to \{0,1\}} \phi_v$$

and that ϕ is unsatisfiable iff ϕ_v is unsatisfiable for all valuations $v \colon \{p_1, \ldots, p_k\} \to \{0,1\}$.

The $\mathrm{QCSP}_2(\mathrm{R}_{1/3})$ instance is true iff every valuation $v \colon \{p_1, \ldots, p_k\} \to \{0,1\}$ can be continued to a valuation $v' \colon \{p_1, \ldots, p_n\} \to \{0,1\}$ such that in each of the clauses $\{C_1, \ldots, C_m\}$ exactly one variable evaluates to true under v' iff, by Claim 3, ϕ_v is unsatisfiable for all $v \colon \{p_1, \ldots, p_k\} \to \{0,1\}$ iff, by the above observation, ϕ is unsatisfiable. ∎

Next we turn to (non-monotone) poor man's logic.

Theorem 4.5. *If* $\{\Box, \Diamond, \wedge, \neg, =\} \subseteq M$ *then* $\mathcal{MDL}(M)$-SAT *is* NEXP-*complete.*

PROOF. Sevenster showed that the problem is in NEXP in the case of $\ovee \notin M$ [Sev09, Lemma 14]. Together with Lemma 4.1 and the fact that $\exists\cdot\mathsf{NEXP} = \mathsf{NEXP}$ the upper bound applies.

For the lower bound we reduce 3CNF-DQBF, which was shown to be NEXP-hard by Peterson et al. [PRA01, Lemma 5.2.2][2], to our problem.

An instance of 3CNF-DQBF consists of universally quantified Boolean variables $p_1, \dots, p_k$, existentially quantified Boolean variables $p_{k+1}, \dots, p_n$, dependence constraints $P_{k+1}, \dots, P_n \subseteq \{p_1, \dots, p_k\}$ and a set of clauses each consisting of three (not necessarily distinct) literals. Here, P_i intuitively states that the value of p_i only depends on the values of the variables in P_i. Now, 3CNF-DQBF is the set of all those instances for which there is a collection of functions $f_{k+1}, \dots, f_n$ with $f_i\colon \{0,1\}^{P_i} \to \{0,1\}$ such that for every valuation $v\colon \{p_1, \dots, p_k\} \to \{0,1\}$ there is at least one literal in each clause that evaluates to true under the valuation $v'\colon \{p_1, \dots, p_n\} \to \{0,1\}$ defined by

$$v'(p_i) := \begin{cases} v(p_i) & \text{if } i \in \{1, \dots, k\} \\ f_i(v \upharpoonright P_i) & \text{if } i \in \{k+1, \dots, n\} \end{cases} .$$

The functions $f_{k+1}, \dots, f_n$ act as restricted existential quantifiers, i. e. for an $i \in \{k+1, \dots, n\}$ the variable p_i can be assumed to be existentially quantified dependent on all universally quantified variables in P_i (and, more importantly, independent of all universally quantified variables not in P_i). Dependencies are thus explicitly specified through the dependence constraints and can contain – but are not limited to – the traditional sequential dependencies, e. g. the quantifier sequence $\forall p_1 \exists p_2 \forall p_3 \exists p_4$ can be modeled by the dependence constraints $P_2 = \{p_1\}$ and $P_4 = \{p_1, p_3\}$.

For the reduction from 3CNF-DQBF to $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg, =)$-SAT we use an idea from Hemaspaandra [Hem01, Theorem 4.2]. There, PSPACE-hardness of $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg)$-SAT over the class $\mathcal{F}_{\leqslant 2}$ of all Kripke structures in which every world has at most two successors is shown. The crucial point in the proof is to ensure that every Kripke structure satisfying the constructed $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg)$ formula adheres to the structure of a complete binary tree and does not contain anything more than this tree. In the class $\mathcal{F}_{\leqslant 2}$ this is automatically the case since in a complete binary tree all worlds already have two successors.

Although in our case there is no such an a priori restriction and therefore we cannot make sure that every satisfying structure is not more than a binary tree, we are able to use dependence atoms to ensure that everything in the structure that does not belong to the tree is essentially nothing else than a copy of a subtree. This will be enough to show the desired reducibility.

---

[2] Peterson et al. showed NEXP-hardness for DQBF without the restriction that the formulas must be in CNF. However, the restriction does not lower the complexity since every propositional formula is satisfiability-equivalent to a formula in CNF whose size is bounded by a polynomial in the size of the original formula.

Let $p_1, \ldots, p_k$ be the universally quantified and $p_{k+1}, \ldots, p_n$ the existentially quantified variables of a 3CNF-DQBF instance φ and let $P_{k+1}, \ldots, P_n$ be its dependence constraints and $\{l_{11}, l_{12}, l_{13}\}, \ldots, \{l_{m1}, l_{m2}, l_{m3}\}$ its clauses. Then the corresponding $\mathcal{MDL}(\Box, \Diamond, \wedge, \neg, {=}())$ formula is

$$\begin{array}{rll} g(\varphi) := & \bigwedge\limits_{i=1}^{n} \Box^{i-1}(\Diamond\Box^{n-i} p_i \wedge \Diamond\Box^{n-i}\overline{p_i}) & (i) \\ \wedge & \bigwedge\limits_{i=1}^{m} \Diamond^{n}(\overline{l_{i1}} \wedge \overline{l_{i2}} \wedge \overline{l_{i3}} \wedge f_i) & (ii) \\ \wedge & \bigwedge\limits_{i=1}^{m} \Box^{n} {=}(l'_{i1}, l'_{i2}, l'_{i3}, f_i) & (iii) \\ \wedge & \Box^{k}\Diamond^{n-k}\big(\overline{f_1} \wedge \ldots \wedge \overline{f_m} \ \wedge \ \bigwedge_{i=k+1}^{n} {=}(P_i, p_i)\big) & (iv) \end{array}$$

where $p_1, \ldots, p_n, f_1, \ldots, f_m$ are atomic propositions and $l'_{ij} := \begin{cases} p & \text{if } l_{ij} = p, \\ p & \text{if } l_{ij} = \overline{p}. \end{cases}$

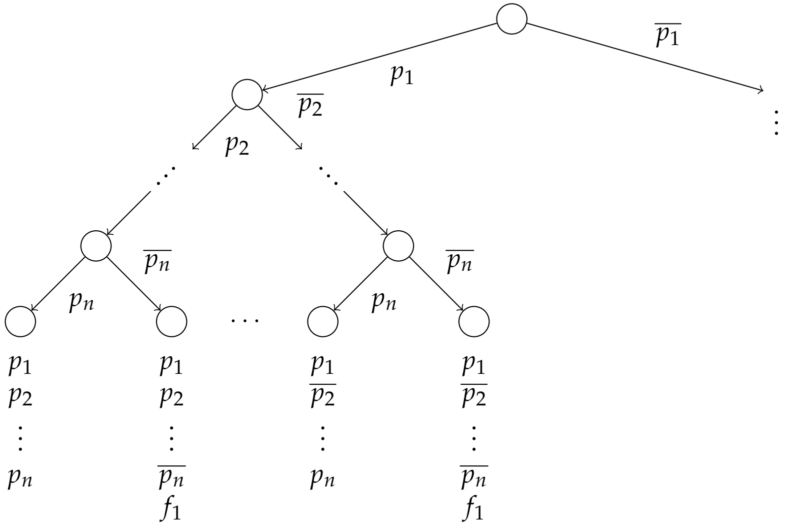
Now if φ is valid, consider the frame which consists of a complete binary tree with n levels (not counting the root) and where each of the 2^n possible labelings of the atomic propositions $p_1, \ldots, p_n$ occurs in exactly one leaf. Additionally, for each $i \in \{1, \ldots, m\}$ f_i is labeled in exactly those leaves in which $l_{i1} \vee l_{i2} \vee l_{i3}$ is false. This frame obviously satisfies (i), (ii) and (iii). And since the modalities in (iv) model the quantors of φ, $\overline{f_i}$ is true exactly in the leaves in which $l_{i1} \vee l_{i2} \vee l_{i3}$ is true and the $=$ atoms in (iv) model the dependence constraints of φ, (iv) is also true and therefore $g(\varphi)$ is satisfied in the root of the tree.

As an example see Figure 4.1 for a frame satisfying $g(\varphi)$ if the first clause in φ is $\{\overline{p_1}, p_n\}$.

If, on the other hand, $g(\varphi)$ is satisfiable, let W be a frame and t a world in W such that $W, \{t\} \models g(\varphi)$. Now (i) enforces W to contain a complete binary tree T with root t such that each labeling of $p_1, \ldots, p_n$ occurs in a leaf of T.

We can further assume w.l.o.g. that W itself is a tree since in $\mathcal{MDL}$ different worlds with identical proposition labelings are indistinguishable and therefore every frame can simply be unwinded to become a tree. Since the modal depth of $g(\varphi)$ is n we can assume that the depth of W is at most n. And since (i) enforces that every path in W from t to a leaf has a length of at least n, all leaves of W lie at levels greater than or equal to n. Altogether we can assume that W is a tree, that all its leaves lie at level n and that it has the same root as T. The only difference is that the degree of W may be greater than that of T.

But we can nonetheless assume that up to level k the degree of W is 2 $(*)$. This is the case because if any world up to level $k-1$ had more successors than the two lying in T, the additional successors could be omitted and (i),



$\overline{p_1}$

p_1 $\overline{p_2}$ ⋮ $\overline{p_n}$ f_1

Figure 4.1: Frame satisfying $g(\phi)$

(ii), (iii) and (iv) would still be fulfilled. For (i), (ii) and (iii) this is clear and for (iv) it holds because (iv) begins with $\Box^k$.

We will now show that, although T may be a proper subframe of W, T is already sufficient to fulfill $g(\phi)$. From this the validity of ϕ will follow immediately.

Claim 1. *$T, \{t\} \models g(\phi)$.*

PROOF OF CLAIM 1. We consider sets of leaves of W that satisfy $\overline{f_1} \wedge \ldots \wedge \overline{f_m} \wedge \bigwedge_{i=k+1}^{n} {=}(P_i, p_i)$ and that can be reached from the set $\{t\}$ by the modality sequence $\Box^k \Diamond^{n-k}$. Let S be such a set and let S be chosen so that there is no other such set that contains less worlds outside of T than S does. Assume there is a $s \in S$ that does not lie in T.

Let $i \in \{1, \ldots, m\}$ and let s' be the leaf in T that agrees with s on the labeling of $p_1, \ldots, p_n$. Then, with $W, \{s\} \models \overline{f_i}$ and (iii), it follows that $W, \{s'\} \models \overline{f_i}$.

Let $S' := (S \backslash \{s\}) \cup \{s'\}$. Then it follows by the previous paragraph that $W, S' \models \overline{f_1} \wedge \ldots \wedge \overline{f_m}$. Since $W, S \models \bigwedge_{i=k+1}^{n} {=}(P_i, p_i)$ and s' agrees with s on the propositions $p_1, \ldots, p_n$ it follows that $W, S' \models \bigwedge_{i=k+1}^{n} {=}(P_i, p_i)$. Hence, S' satisfies $\overline{f_1} \wedge \ldots \wedge \overline{f_m} \wedge \bigwedge_{i=k+1}^{n} {=}(P_i, p_i)$ and as it only differs from S by replacing s with s' it can be reached from $\{t\}$ by $\Box^k\Diamond^{n-k}$ because s and s' agree on $p_1, \dots, p_k$ and, by $(*)$, W does not differ from T up to level k. But this is a contradiction to the assumption since S' contains one world less than S outside of T. Thus, there is no $s \in S$ that does not lie in T and therefore (iv) is fulfilled in T. Since (i), (ii) and (iii) are obviously also fulfilled in T, it follows that $T, \{t\} \models g(\phi)$. ◂

(ii) ensures that for all $i \in \{1, \dots, m\}$ there is a leaf in W in which $\neg(l_{i1} \vee l_{i2} \vee l_{i3}) \wedge f_i$ is true. This leaf can lie outside of T. However, (iii) ensures that all leaves that agree on the labeling of l_{i1}, l_{i2} and l_{i3} also agree on the labeling of f_i. And since there is a leaf where $\neg(l_{i1} \vee l_{i2} \vee l_{i3}) \wedge f_i$ is true, it follows that in all leaves, in which $\neg(l_{i1} \vee l_{i2} \vee l_{i3})$ is true, f_i is true. Conversely, if $\overline{f_i}$ is true in an arbitrary leaf of W then so is $l_{i1} \vee l_{i2} \vee l_{i3}$ $(**)$.

The modality sequence $\Box^k\Diamond^{n-k}$ models the quantors of ϕ and $\bigwedge_{i=k+1}^{n} {=}(P_i, p_i)$ models its dependence constraints. And so there is a bijective correspondence between sets of worlds reachable in T by $\Box^k\Diamond^{n-k}$ from $\{t\}$ and that satisfy $\bigwedge_{i=k+1}^{n} {=}(P_i, p_i)$ on the one hand and truth assignments to $p_1, \dots, p_n$ generated by the quantors of ϕ and satisfying its dependence constraints on the other hand. Additionally, by $(**)$ follows that $\overline{f_1} \wedge \dots \wedge \overline{f_m}$ implies $\bigwedge_{i=1}^{m}(l_{i1} \vee l_{i2} \vee l_{i3})$ and since $T, \{t\} \models g(\phi)$, ϕ is valid. ■

4.1.2 CASES WITH ONLY ONE MODALITY

We will now examine formulas with only one modality.

Theorem 4.6. *Let $M \subseteq \{\Box, \Diamond, \wedge, \vee, \neg, \top, \bot, \varovee\}$ with $\Box \notin M$ or $\Diamond \notin M$. Then the following hold:*

a) $\mathcal{MDL}(M \cup \{=\})$-SAT $\leqslant_m^P$ $\mathcal{MDL}(M \cup \{\top, \bot\})$-SAT, i. e. adding the ${=}(\cdot)$ operator does not increase the complexity if we only have one modality.

b) For every $\mathcal{MDL}(M \cup \{=\})$ formula ϕ it holds that $\varovee$ is equivalent to $\vee$, i. e. ϕ is equivalent to every formula that is generated from ϕ by replacing some or all occurrences of $\varovee$ by $\vee$ and vice versa.

PROOF. Every negation $\neg{=}(\cdot)$ of a dependence atom is by definition always equivalent to $\bot$ and can thus be replaced by the latter. For positive ${=}(\cdot)$ atoms and the $\varovee$ operator we consider two cases.

Case $\Diamond \notin M$. If an arbitrary $\mathcal{MDL}(\Box, \wedge, \vee, \neg, \top, \bot, =, \varovee)$ formula ϕ is satisfiable then it is so in an intransitive singleton frame, i. e. a frame that only contains one world which does not have a successor, because there every subformula that begins with a $\Box$ is automatically satisfied. In a singleton frame all $=(\cdot)$ atoms obviously hold and $\varovee$ is equivalent to $\vee$. Therefore the (un-)satisfiability of ϕ is preserved when substituting every $=(\cdot)$ atom in ϕ with $\top$ and every $\varovee$ with $\vee$ (or vice versa).

Case $\Box \notin M$. If an arbitrary $\mathcal{MDL}(\Diamond, \wedge, \vee, \neg, \top, \bot, =, \varovee)$ formula ϕ is satisfiable then, by the downward closure property, there is a frame W with a world s such that $W, \{s\} \models \phi$. Since there is no $\Box$ in ϕ, every subformula of ϕ is also evaluated in a singleton set (because a $\Diamond$ can never increase the cardinality of the evaluation set). And as in the former case we can replace every $=(\cdot)$ atom with $\top$ and every $\varovee$ with $\vee$ (or vice versa). ■

Thus we obtain the following consequences – note that this takes care of all remaining fragments for the unbounded arity case.

Corollary 4.7. *a) If* $\{\wedge, \neg\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \vee, \neg, \top, \bot, =, \varovee\}$*,* $M \cap \{\vee, \varovee\} \neq \varnothing$ *and* $|M \cap \{\Box, \Diamond\}| = 1$ *then* $\mathcal{MDL}(M)$-SAT *and* $\mathcal{MDL}_k(M)$-SAT *are* NP*-complete for all* $k \geqslant 0$*.*

b) If $\{\wedge, \neg\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \neg, \top, \bot, =\}$ *and* $|M \cap \{\Box, \Diamond\}| = 1$ *then* $\mathcal{MDL}(M)$-SAT $\in$ P*.*

c) If $\{\wedge\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \vee, \top, \bot, =, \varovee\}$ *and* $|M \cap \{\Box, \Diamond\}| = 1$ *then* $\mathcal{MDL}(M)$-SAT $\in$ P*.*

d) If $\wedge \notin M$ *then* $\mathcal{MDL}(M)$-SAT $\in$ P*.*

PROOF. Part a) without the $=(\cdot)$ and $\varovee$ operators is exactly [Hem01, Theorem 6.2(2)]. Theorem 4.6 extends the result to the case with the new operators. Part b) is [Hem01, Theorem 6.4(c,d)] together with Theorem 4.6a for the $=(\cdot)$ operator. Part c) is [Hem01, Theorem 6.4(e,f)] together with Theorem 4.6a,b.

Part d) without $=(\cdot)$ and $\varovee$ is [Hem01, Theorem 6.4(b)]. The proof for the case with the new operators is only slightly different: Let ϕ be an arbitrary $\mathcal{MDL}(M)$ formula. By the same argument as in the proof of Theorem 4.6b we can replace all top-level (i. e. not lying inside a modality) occurrences of $\varovee$ in ϕ with $\vee$ to get the equivalent formula ϕ'. ϕ' is of the form $\Box\psi_1 \vee \ldots \vee \Box\psi_k \vee \Diamond\sigma_1 \vee \ldots \vee \Diamond\sigma_m \vee a_1 \vee \ldots \vee a_s$ where every ψ_i and σ_i is a $\mathcal{MDL}(M)$ formula and every a_i is an atomic formula. If $k > 0$ or any a_i is a literal, $\top$ or a dependence atom then ϕ' is satisfiable. Otherwise it is satisfiable iff one of the σ_i is satisfiable and this can be checked recursively in polynomial time. ■

4.1.3 BOUNDED ARITY DEPENDENCE

Finally, we investigate the remaining fragments for the bounded arity case.

Theorem 4.8. *Let $k \geqslant 0$. Then the following hold:*

*a) If $M \subseteq \{\Box, \Diamond, \wedge, \vee, \neg, \top, \bot, =\}$ then $\mathcal{MDL}_k(M)$-*SAT *$\in$* PSPACE*.*

*b) If $M \subseteq \{\Box, \Diamond, \wedge, \neg, \top, \bot, =\}$ then $\mathcal{MDL}_k(M)$-*SAT *$\in \Sigma_3^{\mathsf{P}}$.*

PROOF. a) Let $\phi \in \mathcal{MDL}_k(M)$. Then by [Sev09, Theorem 6] there is an ordinary modal logic formula ϕ^T which is equivalent to ϕ on singleton sets of evaluation, i. e. for all Kripke structures W and states w in W

$$W, \{w\} \models \phi \quad \text{iff} \quad W, w \models \phi^T.$$

Here ϕ^T is constructed from ϕ in the following way: Let $=(p_{i_{1,1}}, \dots, p_{i_{1,k_1}}, p_{i_{1,k_1+1}}), \dots, =(p_{i_{n,1}}, \dots, p_{i_{n,k_n}}, p_{i_{n,k_n+1}})$ (for $k_1, \dots, k_n \leqslant k$) be all dependence atoms occurring inside ϕ (in an arbitrary order and including multiple occurrences of the same atom in ϕ multiple times) and for all $j \geqslant 0$ let

$$B_j := \{\alpha_f(p_1, \dots, p_j) \mid f \colon \{\top, \bot\}^j \to \{\top, \bot\} \text{ is a total Boolean function}\},$$

where $\alpha_f(p_1, \dots, p_j)$ is a propositional encoding of f, e. g.

$$\alpha_f(p_1, \dots, p_j) := \bigvee_{(i_1, \dots, i_j) \in f^{-1}(\top)} p_1^{i_1} \wedge \dots \wedge p_j^{i_j},$$

with $p^i := \begin{cases} p & \text{if } i = \top \\ \neg p & \text{if } i = \bot \end{cases}$. Note that for all $f \colon \{\top, \bot\}^j \to \{\top, \bot\}$ and all valuations $V \colon \{p_1, \dots, p_j\} \to \{\top, \bot\}$ it holds that $V \models \alpha_f$ iff $f(V(p_1), \dots, V(p_j)) = \top$.

Then ϕ^T is defined as

$$\bigvee_{\alpha_1 \in B_{k_1}} \cdots \bigvee_{\alpha_n \in B_{k_n}} \phi'(\alpha_1, \dots, \alpha_n),$$

where $\phi'(\alpha_1, \dots, \alpha_n)$ is generated from ϕ by replacing each dependence atom $=(p_{i_{\ell,1}}, \dots, p_{i_{\ell,k_\ell}}, p_{i_{\ell,k_\ell+1}})$ with the propositional formula $\alpha_\ell(p_{i_{\ell,1}}, \dots, p_{i_{\ell,k_\ell}}) \leftrightarrow p_{i_{\ell,k_\ell+1}}$. Note that for all $\ell \in \{1, \dots, n\}$ we have that $|\alpha_\ell| \in \mathrm{O}(2^{k_\ell})$ and $|B_{k_\ell}| = 2^{2^{k_\ell}}$. Therefore

$$|\phi^T| \in \prod_{1 \leqslant \ell \leqslant n} 2^{2^{k_\ell}} \cdot |\phi| \cdot \mathrm{O}(2^{k_\ell}) \subseteq \mathrm{O}(\left(2^{2^k}\right)^n \cdot |\phi|).$$

This means that ϕ^T is an exponentially (in the size of ϕ) large disjunction of terms of linear size (remember that k is fixed). ϕ^T is satisfiable if and only if at least one of its terms is satisfiable. Hence we can nondeterministically guess in polynomial time which one of the exponentially many terms should be satisfied and then check in deterministic polynomial space whether this one is satisfiable. The latter is possible because $\phi'(\alpha_1, \dots, \alpha_n)$ is an ordinary modal logic formula and the satisfiability problem for this logic is in PSPACE [Lad77]. Altogether this leads to $\mathcal{MDL}_k(M)$-SAT $\in \exists\cdot$PSPACE $=$ PSPACE.

b) In this case we cannot use the same argument as before without modifications since that would only lead to a PSPACE upper bound again. The problem is that in the contruction of ϕ^T we introduce the subformulas α_ℓ and these may contain the $\vee$ operator. We can, however, salvage the construction by looking inside Ladner's PSPACE algorithm [Lad77, Theorem 5.1]. For convenience we restate (a slightly modified form of) it in Algorithm 4.1. It holds for all ordinary modal logic formulas ϕ that ϕ is satisfiable (by a Kripke structure from the class K) if and only if satisfiable($\{\phi\}$, $\varnothing$, $\varnothing$)=`true`.

Algorithm 4.1: satisfiable(T,A,E)

```
if $T \nsubseteq$ Atomic then    //Atomic denotes the set of atomic propositions, their negations
                                 //and the constants $\top$ and $\bot$
  choose $\psi \in T \setminus$Atomic    //deterministically (but arbitrarily)
  set $T' := T \setminus \{\psi\}$
  if $\psi = \psi_1 \wedge \psi_2$ then
    return satisfiable($T' \cup \{\psi_1, \psi_2\}$, $A$, $E$)
  elseif $\psi = \psi_1 \vee \psi_2$ then
    nondeterministically existentially guess $i \in \{1,2\}$
    return satisfiable($T' \cup \{\psi_i\}$, $A$, $E$)
  elseif $\psi = \Box\psi_1$ then
    return satisfiable($T'$, $A \cup \{\psi_1\}$, $E$)
  elseif $\psi = \Diamond\psi_1$ then
    return satisfiable($T'$, $A$, $E \cup \{\psi_1\}$)
  end
else
  if $T$ is consistent then
    if $E \neq \varnothing$
      nondeterministically universally guess $\psi \in E$
      return satisfiable($A \cup \{\psi\}$, $\varnothing$, $\varnothing$)
    else
      return true
    end
  else
```

```
    return false
  end
end
```

The algorithm works in a top-down manner and runs in alternating polynomial time. It universally guesses when encountering a $\Box$ operator and existentially guesses when encountering a $\vee$ operator – in all other cases it is deterministic. Now, to check whether ϕ^T is satisfiable we first existentially guess which of the exponentially many terms should be satisfied and then check whether this term $\phi'(\alpha_1, \dots, \alpha_n)$ is satisfiable by invoking satisfiable($\{\phi'(\alpha_1, \dots, \alpha_n)\}, \emptyset, \emptyset$).

To see that this in fact gives us a Σ_3^{P}-algorithm note that ϕ does not contain any disjunctions. Hence also $\phi'(\alpha_1, \dots, \alpha_n)$ contains no disjunctions apart from the ones that occur inside one of the subformulas $\alpha_1, \dots, \alpha_n$. Therefore Algorithm 4.1 does not do any nondeterministic existential branching apart from when processing an α_i. But in the latter case it is impossible to later nondeterministically universally branch because univeral guessing only occurs when processing a $\Box$ operator and these cannot occur inside an α_i, since these are purely propositional formulas. Therefore the algorithm, if run on a formula $\phi'(\alpha_1, \dots, \alpha_n)$ as input, is essentially a Π_2^{P} algorithm. Together with the existential guessing of the term in the beginning we get that $\mathcal{MDL}_k(M)$-SAT $\in \exists\cdot\Pi_2^{\mathsf{P}} = \Sigma_3^{\mathsf{P}}$. ■

Theorem 4.9. *If* $\{\Box, \Diamond, \wedge, \neg, =\} \subseteq M$ *then* $\mathcal{MDL}_3(M)$-SAT *is* Σ_3^{P}*-hard.*

PROOF. We use the same construction as in the hardness proof for Theorem 4.5 to reduce the problem 3CNF-QBF$_3$, which was shown to be Σ_3^{P}-complete by Wrathall [Wra77, Corollary 6], to our problem. 3CNF-QBF$_3$ is the set of all propositional sentences of the form

$$\exists p_1 \dots \exists p_k \forall p_{k+1} \dots \forall p_\ell \exists p_{\ell+1} \dots \exists p_n \bigwedge_{i=1}^{m} (l_{i1} \vee l_{i2} \vee l_{i3}),$$

where the l_{ij} are literals over $p_1, \dots, p_n$, which are valid.

Now let ϕ be a 3CNF-QBF$_3$ instance, let $p_1, \dots, p_n$ be its variables and let $k, \ell, m, (l_{ij})_{\substack{i=1,\dots,m\\ j=1,2,3}}$ be as above. Then the corresponding $\mathcal{MDL}_3(\Box, \Diamond, \wedge, \neg, =)$

formula is

$$
\begin{aligned}
g(\varphi) := \quad & \bigwedge_{i=1}^{n} \Box^{i-1}(\Diamond\Box^{n-i}p_i \wedge \Diamond\Box^{n-i}\overline{p_i}) && (i)\\
\wedge \quad & \bigwedge_{i=1}^{m} \Diamond^{n}(\overline{l_{i1}} \wedge \overline{l_{i2}} \wedge \overline{l_{i3}} \wedge f_i) && (ii)\\
\wedge \quad & \bigwedge_{i=1}^{m} \Box^{n}{=}(l'_{i1}, l'_{i2}, l'_{i3}, f_i) && (iii)\\
\wedge \quad & \Diamond^{k}\Box^{\ell-k}\Diamond^{n-\ell}({=}(p_1) \wedge \ldots \wedge {=}(p_k) \;\wedge\; \overline{f_1} \wedge \ldots \wedge \overline{f_m}) && (iv)
\end{aligned}
$$

where $p_1, \ldots, p_n, f_1, \ldots, f_m$ are atomic propositions and $l'_{ij} := \begin{cases} p & \text{if } l_{ij} = p, \\ p & \text{if } l_{ij} = \overline{p}. \end{cases}$

The proof that g is a correct reduction is essentially the same as for Theorem 4.5 (also see Figure 4.1 for an example of a typical Kripke structure satisfying $g(\varphi)$). The only difference is that there we had arbitrary dependence atoms in part *(iv)* of $g(\varphi)$ whereas here we only have 0-ary dependence atoms. This difference is due to the fact that there we had to be able to express arbitrary dependencies because we were reducing from 3CNF-DQBF whereas here we only have two kinds of dependencies for the existentially quantified variables: either complete constancy (for the variables that get quantified before any universal variable does) or complete freedom (for the variables that get quantified after all universal variables are already quantified). The former can be expressed by 0-ary dependence atoms and for the latter we simply omit any dependence atoms.

Note that it might seem as if with the same construction even Σ_k^p-hardness for arbitrary k could be proved by having more alternations between the two modalities in part *(iv)* of $g(\varphi)$. The reason that this does not work is that we do not really ensure that a structure fulfilling $g(\varphi)$ is not more than a binary tree, e. g. it can happen that the root node of the tree has three successors: one in whose subtree all leaves on level n are labeled with p_1, one in whose subtree no leaves are labeled with p_1 and one in whose subtree only some leaves are labeled with p_1. Now, the first diamond modality can branch into this third subtree and then the value of p_1 is not yet determined. Hence the modalities alone are not enough to express alternating dependencies and hence we need the $=(p_i)$ atoms in part *(iv)* to ensure constancy. ∎

Corollary 4.10. *a) Let $k \geqslant 0$ and $\{\Box, \Diamond, \wedge, \vee, \neg\} \subseteq M$. Then $\mathcal{MDL}_k(M)$-*SAT *is* PSPACE*-complete.*

*b) Let $k \geqslant 3$ and $\{\Box, \Diamond, \wedge, \neg, =\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \neg, \top, \bot, =, \varovee\}$. Then $\mathcal{MDL}_k(M)$-*SAT *is Σ_3^{P}-complete.*

PROOF. The lower bound for a) is due to the PSPACE-completeness of ordinary modal logic satisfiability which was shown in [Lad77]. The upper bound follows from Theorem 4.8a, Lemma 4.1b and the fact that $\exists{\cdot}\mathsf{PSPACE} = \mathsf{PSPACE}$.

The lower bound for b) is Theorem 4.9. The upper bound follows from Theorem 4.8b, Lemma 4.1 and $\exists{\cdot}\Sigma_3^{\mathsf{P}} = \Sigma_3^{\mathsf{P}}$. ■

Note that in Corollary 4.10b we require that $k \geqslant 3$. This is due to the fact that the reduction in our proof of Theorem 4.9 needs ternary dependence atoms. With $k \leqslant 2$ this reduction does not work and thus the lower bound remains open in that case.

4.2 MODEL CHECKING

Now that we have classified the operator fragments of $\mathcal{MDL}$ with respect to the complexity of satisfiability we turn over to model checking and do the same. We will investigate – according to Definition 2.20 – for all $M \subseteq \{\Box, \Diamond, \wedge, \vee, \otimes, \neg, =\}$ and all $k \geqslant 0$ the problem

Problem: $\mathcal{MDL}(M)$-MC ($\mathcal{MDL}_k(M)$-MC)
Input: An $\mathcal{MDL}(M)$ (resp. $\mathcal{MDL}_k(M)$) formula ϕ, a Kripke structure $K = (S, R, \pi)$ and a team $T \subseteq S$.
Question: $K, T \models \phi$?

The first lemma shows that whether to include $\top$, $\bot$ or $\neg$ in a sublogic $\mathcal{MDL}(M)$ of $\mathcal{MDL}$ does not affect the complexity of $\mathcal{MDL}(M)$-MC .

Lemma 4.11. *Let M be an arbitrary set of $\mathcal{MDL}$ operators, i. e. $M \subseteq \{\Box, \Diamond, \wedge, \vee, \otimes, \neg, =, \bot, \top\}$. Then it holds that*

$$\mathcal{MDL}(M)\text{-MC} \ \equiv_{\mathrm{m}}^{\mathsf{P}} \ \mathcal{MDL}(M \backslash \{\top, \bot, \neg\})\text{-MC}.$$

PROOF. It suffices to show $\leqslant_{\mathrm{m}}^{\mathsf{P}}$. So let $K = (S, R, \pi)$ be a Kripke structure, $T \subseteq S$, $\phi \in \mathcal{MDL}(M)$ and $\mathrm{Var}(\phi) = \{p_1, \ldots, p_n\}$. Let $p'_1, \ldots, p'_n, t, f$ be fresh propositional variables. Then $K, T \models \phi$ iff $K', T \models \phi'$, where $K' := (S, R, \pi')$ with π' defined by

$$\begin{aligned} \pi'(s) \cap \{t, f\} &:= \{t\}, \\ \pi'(s) \cap \{p_i, p'_i\} &:= \begin{cases} \{p_i\} & \text{if } p_i \in \pi(s), \\ \{p'_i\} & \text{if } p_i \notin \pi(s), \end{cases} \end{aligned}$$

for all $i \in \{1, \dots, n\}$ and $s \in S$, and $\phi \in \mathcal{MDL}(M \backslash \{\top, \bot, \neg\})$ defined by

$$\phi' := \phi(p'_1/\neg p_1)(p'_2/\neg p_2) \dots (p'_n/\neg p_n)(t/\top)(f/\bot). \qquad \blacksquare$$

Now we will show that the most general of our problems is in NP and therefore all model checking problems investigated later are as well.

Proposition 4.12. *Let M be an arbitrary set of $\mathcal{MDL}$ operators. Then $\mathcal{MDL}(M)$-MC is in NP. And hence also $\mathcal{MDL}_k(M)$-MC is in NP for every $k \geqslant 0$.*

PROOF. The following non-deterministic top-down algorithm clearly checks the truth of the formula ϕ on the Kripke structure W in the evaluation set T in polynomial time.

Algorithm 4.2: check($W = (S, R, \pi)$,ϕ,T)

```
case $\phi$

when $\phi = \top$
  return true

when $\phi = \bot$
  return false

when $\phi = p$
  foreach $s \in T$
    if not $p \in \pi(s)$ then
      return false
  return true

when $\phi = \neg p$
  foreach $s \in T$
    if $p \in \pi(s)$ then
      return false
  return true

when $\phi = =(p_1, \dots, p_n)$
  foreach $(s, s') \in T \times T$
    if $\pi(s) \cap \{p_1, \dots, p_{n-1}\} = \pi(s') \cap \{p_1, \dots, p_{n-1}\}$ then
          // i. e. $s$ and $s'$ agree on the valuations of the propositions $p_1, \dots, p_{n-1}$
      if ($q \in \pi(s)$ and not $q \in \pi(s')$) or (not $q \in \pi(s)$ and $q \in \pi(s')$) then
        return false
  return true
```

```
when $\phi = \psi \vee \theta$
  guess two sets of states $A, B$ with $A \cup B = T$
  return (check($W, A, \psi$) and check($W, B, \theta$))

when $\phi = \psi \owedge \theta$
  return (check($W, T, \psi$) or check($W, T, \theta$))

when $\phi = \psi \wedge \theta$
  return (check($W, T, \psi$) and check($W, T, \theta$))

when $\phi = \Box\psi$
  $T' := \varnothing$
  foreach $s' \in S$
    foreach $s \in T$
      if $(s, s') \in R$ then
        $T' := T' \cup \{s'\}$
          // $T'$ is the set of all successors of all states in $T$, i.e. $T' = R(T)$
  return check($W, T', \psi$)

when $\phi = \Diamond\psi$
  guess set of states $T' \subseteq S$
    foreach $s \in T$
      if there is no $s' \in T'$ with $(s, s') \in R$ then
        return false
          // $T'$ contains at least one successor of every state in $T$, i.e. $T' \in \langle T \rangle$
  return check($W, T', \psi$)
```

The algorithm runs in polynomial time since it processes each subformula of ϕ in polynomial time and exactly once. ■

4.2.1 UNBOUNDED ARITY FRAGMENTS

We now focus on the cases with unbounded arity dependence atoms – though sometimes our results directly carry over to the bounded cases.

We first show that the model checking problem is NP-hard in general and that this still holds without modalities.

Theorem 4.13. *Let* $\{\wedge, \vee, =\} \subseteq M$. *Then* $\mathcal{MDL}(M)$-MC *is* NP*-complete. Furthermore,* $\mathcal{MDL}_k(M)$-MC *is* NP*-complete for every* $k \geqslant 0$.

PROOF. Membership in NP follows from Proposition 4.12. For the hardness proof we reduce from 3SAT to $\mathcal{MDL}_0(\wedge, \vee, =)$-MC.

For this purpose let $\phi = C_1 \wedge \ldots \wedge C_m$ be an arbitrary 3CNF formula with variables $x_1, \ldots, x_n$. Let W be the Kripke structure (S, R, π) over the atomic propositions $r_1, \ldots, r_n, p_1, \ldots, p_n$ defined by

$$\begin{aligned} S &:= \{s_1, \ldots, s_m\}, \\ R &:= \varnothing, \\ \pi(s_i) \cap \{r_j, p_j\} &:= \begin{cases} \{r_j, p_j\} & \text{iff } x_j \text{ occurs in } C_i \text{ positively,} \\ \{r_j\} & \text{iff } x_j \text{ occurs in } C_i \text{ negatively,} \\ \varnothing & \text{iff } x_j \text{ does not occur in } C_i. \end{cases} \end{aligned}$$

Let ψ be the $\mathcal{MDL}_0(\wedge, \vee, =)$ formula

$$\bigvee_{j=1}^{n} r_j \wedge =(p_j)$$

and let $T := \{s_1, \ldots, s_m\}$ be the evaluation set.

We will show that $\phi \in$ 3SAT iff $W, T \models \psi$. Then it follows that 3SAT $\leqslant^{\mathrm{P}}_{\mathrm{m}}$ $\mathcal{MDL}_0(M)$-MC and therefore $\mathcal{MDL}_0(M)$-MC is NP-hard.

Now assume that $\phi \in$ 3SAT and that θ is a satisfying valuation for ϕ. From the valuations $\theta(x_j)$ of all x_j we construct subteams $T_1, \ldots, T_n$ such that for all $j \in \{1, \ldots, n\}$ it holds that $W, T_j \models r_j \wedge =(p_j)$. The T_j are constructed as follows:

$$T_j := \begin{cases} \{s_i \in S \mid \pi(s_i) \cap \{r_j, p_j\} = \{r_j, p_j\}\} & \text{iff } \theta(x_j) = 1, \\ \{s_i \in S \mid \pi(s_i) \cap \{r_j, p_j\} = \{r_j\}\} & \text{iff } \theta(x_j) = 0, \end{cases}$$

i. e. T_j is the team consisting of exactly the states corresponding to clauses satisfied by $\theta(x_j)$.

Since every clause in ϕ is satisfied by some valuation $\theta(x_j) = 1$ or $\theta(x_j) = 0$ we have that $T_1 \cup \ldots \cup T_n = T$ such that $W, T \models \phi$.

On the other hand, assume that $W, T \models \psi$, therefore we have $T = T_1 \cup T_2 \cup \ldots \cup T_n$ such that for all $j \in \{1, \ldots, n\}$ it holds that $T_j \models r_j \wedge =(p_j)$. Therefore $\pi(s_i) \cap \{p_j\}$ is constant for all elements $s_i \in T_j$. From this we can construct a satisfying valuation θ for ϕ.

For all j let $I_j := \{i \mid s_i \in T_j\}$. For every $j \in \{1, \ldots, n\}$ we consider T_j. If for every element $s_i \in T_j$ it holds that $\pi(s_i) \cap \{p_j\} = \{p_j\}$ then we have for all $i \in I_j$ that x_j is a literal in C_i. In order to satisfy those C_i we set $\theta(x_j) = 1$. If for every element $s_i \in T_j$ it holds that $\pi(s_i) \cap \{p_j\} = \varnothing$ then we have for every $i \in I_j$ that $\neg x_j$ is a literal in C_i. In order to satisfy those C_i we set $\theta(x_j) = 0$. Since for every $s_i \in T$ there is a j with $s_i \in T_j$ we have an evaluation θ that satisfies every clause in ϕ. Therefore we have $\theta \models \phi$. ■

Instead of not having modalities at all, we can also allow nothing but the $\Diamond$ modality, i. e. we disallow propositional connectives and the $\Box$ modality, and model checking is NP-complete as well.

Theorem 4.14. *Let* $\{\Diamond, =\} \subseteq M$*. Then* $\mathcal{MDL}(M)$-MC *is* NP*-complete.*

PROOF. Membership in NP follows from Proposition 4.12 again.

For hardness we again reduce from 3SAT. Let $\varphi = \bigwedge_{i=1}^{m} C_i$ be an arbitrary 3CNF formula built from the variables $x_1, \ldots, x_n$. Let W be the Kripke structure (S, R, π), over the atomic propositions $p_1, \ldots, p_n, q$, shown in Figure 4.2 and formally defined by

$$\begin{aligned} S &:= \{c_1, \ldots, c_m, s_1^1, \ldots, s_n^1, s_1^0, \ldots, s_n^0\}, \\ R \cap \{(c_i, s_j^1), (c_i, s_j^0)\} &:= \begin{cases} \{(c_i, s_j^1)\} & \text{iff } x_j \text{ occurs in } C_i \text{ positively,} \\ \{(c_i, s_j^0)\} & \text{iff } x_j \text{ occurs in } C_i \text{ negatively,} \\ \varnothing & \text{iff } x_j \text{ does not occur in } C_i, \end{cases} \\ \pi(c_i) &:= \varnothing, \\ \pi(s_j^1) &:= \{p_j, q\}, \\ \pi(s_j^0) &:= \{p_j\}. \end{aligned}$$

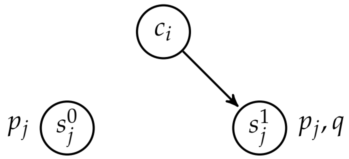

Figure 4.2: Kripke structure part corresponding to the 3CNF clause $C_i = x_j$.

Let ψ be the $\mathcal{MDL}(\Diamond, =)$ formula $\Diamond{=}(p_1, \ldots, p_n, q)$ and let $T := \{c_1, \ldots, c_m\}$. Then we will show that $\varphi \in$ 3SAT iff $W, T \models \psi$. Hence, 3SAT $\leqslant_{\mathrm{m}}^{\mathsf{P}}$ $\mathcal{MDL}(M)$-MC and $\mathcal{MDL}(M)$-MC is NP-hard.

First suppose we have a satisfying valuation θ for φ. From θ we will construct a successor team T' of T, i. e. for all $s \in T$ there is an $s' \in T'$ s.t. $(s, s') \in R$ with $W, T' \models {=}(p_1, \ldots, p_n, q)$. T' is defined by:

$$T' := \{s_j^z \mid \theta(x_j) = z, j \in \{1, \ldots, n\}\}$$

Since θ satisfies every clause C_i of ϕ we have that for every C_i there is an x_j with

$$\theta(x_j) = \begin{cases} 1, & \text{iff } x_j \in C_i \\ 0, & \text{iff } \neg x_j \in C_i. \end{cases}$$

It follows that for every $s \in T$ there is an $s' \in T'$ such that $(s, s') \in R$.

By construction of T' it is not possible to have both s_j^0 and s_j^1 in T'. Hence for all elements $s_j^0, s_{j'}^1 \in T'$ it follows that $j \neq j'$ and therefore $\pi(s_j^0) \cap \{p_1, \ldots, p_n\} \neq \pi(s_{j'}^1) \cap \{p_1, \ldots, p_n\}$. Thus $W, T' \models {=}(p_1, \ldots, p_n, q)$.

On the other hand assume $W, T \models \psi$. Then there is a successor set T' of T s.t. for every $s \in T$ there is an $s' \in T'$ with $(s, s') \in R$ and $T' \models {=}(p_1, \ldots, p_n, q)$. We construct θ as follows:

$$\theta(x_j) := \begin{cases} 1, & \text{iff } s_j^1 \in T' \\ 0, & \text{iff } s_j^0 \in T' \\ 0, & \text{iff } s_j^0, s_j^1 \notin T'. \end{cases}$$

Note that in the latter case it does not matter if 0 or 1 is chosen.

Since $W, T' \models {=}(p_1, \ldots, p_n, q)$ and for every j it holds that $W, \{s_j^0, s_j^1\} \not\models {=}(p_1, \ldots, p_n, q)$ we have that for every j at most one of s_j^0 or s_j^1 is in T'. It follows that θ is well-defined.

Since for every $c_i \in T$ there is an $s_j^z \in T'$ s.t. $(c_i, s_j^z) \in R$ with $\theta(x_j) = z$, we have by contruction of W that θ satisfies every clause C_i of ϕ. From this follows $\phi \in$ 3SAT. ∎

If we disallow $\Diamond$ but allow $\Box$ instead we have to also allow $\vee$ to get NP-hardness.

Theorem 4.15. *Let* $\{\Box, \vee, =\} \subseteq M$. *Then* $\mathcal{MDL}(M)$-MC *is* NP-*complete. Also,* $\mathcal{MDL}_k(M)$-MC *is* NP-*complete for every* $k \geqslant 0$.

PROOF. Membership in NP follows from Proposition 4.12 again. To prove hardness, we reduce 3SAT to $\mathcal{MDL}_0(\Box, \vee, =)$-MC. Before we formally define the reduction and prove its correctness let us demonstrate its general idea with a concrete example.

Example 4.16. Let ϕ be the 3CNF formula

$$\underbrace{(\neg x_1 \vee x_2 \vee x_3)}_{C_1} \wedge \underbrace{(x_2 \vee \neg x_3 \vee x_4)}_{C_2} \wedge \underbrace{(x_1 \vee \neg x_2)}_{C_3}.$$

Now we have to construct a corresponding Kripke structure $W = (S, R, \pi)$, a team $T \subseteq S$ and a $\mathcal{MDL}(\Box, \vee, =)$ formula ψ such that $\phi \in$ 3Sat iff $W, T \models \psi$.

The structure W is shown in Figure 4.3. It has *levels* 0 to 4 where the jth level (for $j \geqslant 1$ corresponding to the variable x_j in the formula ϕ) is the set of nodes reachable via exactly j transitions from the set of nodes s_1, s_2 and s_3 (corresponding to the clauses of ϕ).

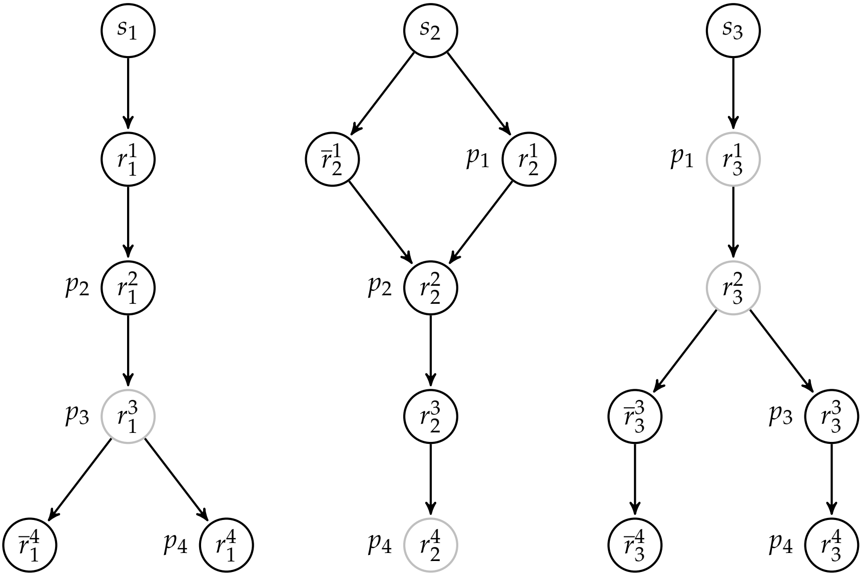

Figure 4.3: Kripke structure corresponding to $\phi = (\neg x_1 \vee x_2 \vee x_3) \wedge (x_2 \vee \neg x_3 \vee x_4) \wedge (x_1 \vee \neg x_2)$

The formula ψ is

$$\underbrace{\Box{=}(p_1)}_{\gamma_1} \vee \underbrace{\Box\Box{=}(p_2)}_{\gamma_2} \vee \underbrace{\Box\Box\Box{=}(p_3)}_{\gamma_3} \vee \underbrace{\Box\Box\Box\Box{=}(p_4)}_{\gamma_4}.$$

And the team T is $\{s_1, s_2, s_3\}$.

Now suppose that $W, T \models \psi$. Then, for all $j \in \{1, \ldots, 4\}$ let $T_j \subseteq T$ with $T_j \models \gamma_j$ and $T_1 \cup \ldots \cup T_4 = T$. By comparing the formulas γ_j with the chains in the Kripke structure one can easily verify that $T_1 \subsetneqq \{s_1, s_3\}$, i.e. there can at most be one of s_1 and s_3 in T_1 since $\pi(r_1^1) \cap p_1 \neq \pi(r_3^1) \cap \{p_1\}$ and s_2 cannot be in T_1 since its direct successors $\bar{r}_2^1, r_2^1$ do not agree on p_1. In this case $T_1 = \{s_1\}$

means that C_1 is satisfied by setting $\theta(x_1) = 0$ and the fact that $\{s_2\} \not\models \gamma_1$ corresponds to the fact that there is no way to satisfy C_2 via x_1, because x_1 does not occur in C_2. Analogously, $T_2 \subseteq \{s_1, s_2\}$ or $T_2 \subseteq \{s_3\}$, and $T_3 \subsetneq \{s_1, s_2\}$ and $T_4 \subseteq \{s_2\}$.

Now, for example, the valuation θ where x_1, x_3 and x_4 evaluate to true and x_2 to false satisfies ϕ. From this valuation one can construct sets $T_1, \dots, T_4$ with $T_1 \cup \ldots \cup T_4 = \{s_1, s_2, s_3\}$ such that $T_j \models \gamma_j$ for all $j = 1, \dots, 4$ by defining $T_j := \{s_i \mid x_j \text{ satisfies clause } C_i \text{ under } \theta\}$ for all j. This leads to $T_1 = T_2 = \{s_3\}$, $T_3 = \{s_1\}$ and $T_4 = \{s_2\}$.

The gray colourings indicate which chains (resp. clauses) are satisfied on which levels (resp. by which variables). ψ (resp. ϕ) is satisfied because there is a gray coloured state in each chain.

⌟

Now, in general, let $\phi = \bigwedge_{i=1}^{m} C_i$ be an arbitrary 3CNF formula over the variables $x_1, \dots, x_n$. Let W be the Kripke structure (S, R, π) over the atomic propositions $p_1, \dots, p_n$ shown in Figures 4.4 to 4.9 and formally defined as follows:

$$\begin{aligned} S \quad := \quad & \{s_i | i \in \{1, \dots, m\}\} \\ & \cup \{r^j_k | k \in \{1, \dots, m\}, j \in \{1, \dots, n\}\} \\ & \cup \{\overline{r}^j_k | k \in \{1, \dots, m\}, j \in \{1, \dots, n\}\} \end{aligned}$$

$$R \cap \bigcup_{j \in \{1,\dots,n\}} \{(s_i, r^j_i), (s_i, \overline{r}^j_i)\} \;:=$$

$$\begin{cases} \{(s_i, r^1_i)\} & \text{iff } x_1 \text{ occurs in } C_i \text{ (positively or negatively)} \quad \textit{(Fig. 4.4)} \\ \{(s_i, r^1_i), (s_i, \overline{r}^1_i)\} & \text{iff } x_1 \text{ does not occur in } C_i \quad \textit{(Fig. 4.5)} \end{cases}$$

$$R \cap \bigcup_{k \in \{1,\dots,n\}} \{(r^j_i, r^k_i), (r^j_i, \overline{r}^k_i), (\overline{r}^j_i, r^k_i), (\overline{r}^j_i, \overline{r}^k_i)\} \;:=$$

$$\begin{cases} \{(r^j_i, r^{j+1}_i)\} & \text{iff } x_j \text{ and } x_{j+1} \text{ both occur in } C_i \quad \textit{(Fig. 4.6)} \\ \{(r^j_i, r^{j+1}_i), (r^j_i, \overline{r}^{j+1}_i)\} & \text{iff } x_j \text{ occurs in } C_i \text{ but } x_{j+1} \text{ does not occur in } C_i \quad \textit{(Fig. 4.7)} \\ \{(r^j_i, r^{j+1}_i), (\overline{r}^j_i, r^{j+1}_i)\} & \text{iff } x_j \text{ does not occur in } C_i \text{ but } x_{j+1} \text{ does occur in } C_i \quad \textit{(Fig. 4.8)} \\ \{(r^j_i, r^{j+1}_i), (\overline{r}^j_i, \overline{r}^{j+1}_i)\} & \text{iff neither } x_j \text{ nor } x_{j+1} \text{ occur in } C_i \quad \textit{(Fig. 4.9)} \end{cases}$$

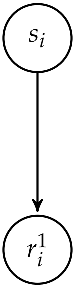

Figure 4.4: x_1 occurs in C_i.

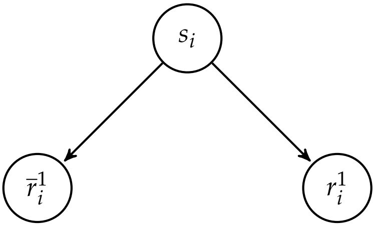

Figure 4.5: x_1 does not occur in C_i.

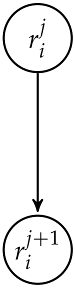

Figure 4.6: x_j and x_{j+1} occur in C_i.

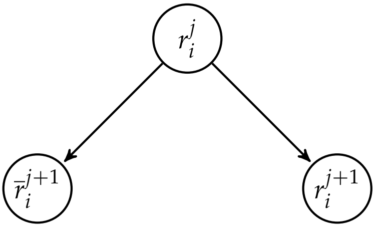

Figure 4.7: x_j occurs in C_i but x_{j+1} does not occur in C_i.

$$\begin{array}{rcl} \pi(s_i) & := & \varnothing \\ \pi(r_i^j) & := & \begin{cases} \{p_j\} & \text{iff } x_j \text{ occurs in } C_i \text{ positively or not at all} \\ \varnothing & \text{iff } x_j \text{ occurs in } C_i \text{ negatively} \end{cases} \\ \pi(\overline{r}_i^j) & := & \varnothing \end{array}$$

Let ψ be the $\mathcal{MDL}(\Box, \vee, =)$ formula

$$\bigvee_{j=1}^{n} \Box^j {=}(p_j)$$

and let $T := \{s_1, \ldots, s_m\}$.

Then, as we will show, $\phi \in$ 3SAT iff $W, T \models \psi$ and therefore $\mathcal{MDL}_0(\Box, \vee, =)$-MC is NP-complete. Intuitively, the direction from left to right holds because the disjunction splits the team $\{s_1, \ldots, s_m\}$ of all starting points of

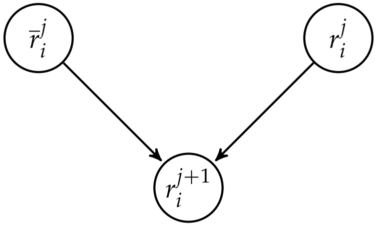

Figure 4.8: x_j does not occur in C_i but x_{j+1} does occur in C_i.

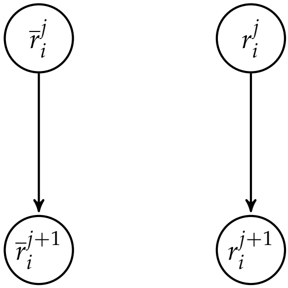

Figure 4.9: x_j and x_{j+1} do not occur in C_i.

chains of length n into n subsets (one for each variable) in the following way: s_i is in the subset that belongs to x_j iff x_j satisfies the clause C_i under the variable valuation that satisfies ϕ. Then the team that belongs to x_j collectively satisfies the disjunct $\Box^j{=}(p_j)$ of ψ. For the reverse direction the $\overline{r}_i^j$ states are needed to ensure that a state s_i can only satisfy a disjunct $\Box^j{=}(p_j)$ if there is a variable x_j that occurs in clause C_i (positively or negatively) and satisfies C_i.

More precisely, assume that θ is a satisfying valuation for ϕ. From θ we construct subteams $T_1, \ldots, T_n$ with $T_1 \cup \ldots \cup T_n = T$ s.t. for all j it holds that $T_j \models \Box^j{=}(p_j)$. T_j is defined by

$$T_j := \begin{cases} \{s_i \mid \{s_i\} \models \Box^j p_j\} & \text{iff } \theta(x_j) = 1 \\ \{s_i \mid \{s_i\} \models \Box^j \neg p_j\} & \text{iff } \theta(x_j) = 0 \end{cases}$$

for all $j \in \{1, \ldots, n\}$. Obviously, for all j it holds that $T_j \models \Box^j{=}(p_j)$. Now we will show that for all $i \in \{1, \ldots, m\}$ there is a $j \in \{1, \ldots, n\}$ such that $s_i \in T_j$. For this purpose let $i \in \{1, \ldots, m\}$ and suppose C_i is satisfied by $\theta(x_j) = 1$ for a $j \in \{1, \ldots, n\}$. Then, by definition of W, $\pi(r_i^j) = p_j$, hence $\{s_i\} \models \Box^j p_j$ and therefore $s_i \in T_j$. If, on the other hand, C_i is satisfied by $\theta(x_j) = 0$ then we have that $\pi(r_i^j) = \varnothing$, hence $\{s_i\} \models \Box^j \neg p_j$ and again it follows that $s_i \in T_j$. Altogether we have that for all i there is a j such that $s_i \in T_j$. It follows that $T_1 \cup \ldots \cup T_n = T$ and therefore $W, T \models \psi$.

On the other hand assume $W, T \models \psi$. Therefore we have $T = T_1 \cup \ldots \cup T_n$ with $T_j \models \Box^j{=}(p_j)$ for all $j \in \{1, \ldots, n\}$. We define a valuation θ by

$$\theta(x_j) := \begin{cases} 1 & \text{iff } T_j \models \Box^j p_j \\ 0 & \text{iff } T_j \models \Box^j \neg p_j. \end{cases}$$

Since every s_i is contained in a T_j we know that for all $i \in \{1, \ldots, m\}$ there is a $j \in \{1, \ldots, n\}$ with $\{s_i\} \models \Box^j{=}(p_j)$. From this it follows that x_j occurs in C_i (positively or negatively) since otherwise, by definition of W, both r_i^j and $\overline{r}_i^j$ would be reachable from s_i.

It also holds that $\{s_i\} \models \Box^j p_j$ or $\{s_i\} \models \Box^j \neg p_j$. In the former case we have that $\pi(r_i^j) = p_j$, hence, by definition of W, x_j is a literal in C_i. By construction of θ it follows that C_i is satisfied. In the latter case it holds that $\overline{x}_j$ is a literal in C_i. Again, by construction of θ it follows that C_i is satisfied. Hence, $\phi \in$ 3SAT. ■

If we disallow both $\Diamond$ and $\vee$ the problem becomes tractable since the non-deterministic steps in the model checking algorithm are no longer needed.

Theorem 4.17. *Let $M \subseteq \{\Box, \wedge, \otimes, \neg, =\}$. Then $\mathcal{MDL}(M)$-MC is in* P.

PROOF. Algorithm 4.2 is a non-deterministic algorithm that checks the truth of an arbitrary $\mathcal{MDL}$ formula in a given structure in polynomial time. Since $M \subseteq \{\Box, \wedge, \otimes, \neg, =\}$ it holds that $\Diamond, \vee \notin M$. Therefore the non-deterministic steps are never used and the algorithm is in fact deterministic in this case. ■

Note that this deterministic polynomial time algorithm is a top-down algorithm and therefore works in a fundamentally different way than the usual deterministic polynomial time bottom-up model checking algorithm for plain modal logic.

Now we have seen that $\mathcal{MDL}(M)$-MC is tractable if $\vee \notin M$ and $\Diamond \notin M$ since these two operators are the only source of non-determinism. On the other hand, $\mathcal{MDL}(M)$-MC is NP-complete if $=(\cdot) \in M$ and either $\Diamond \in M$ (Theorem 4.14) or $\vee, \Box \in M$ (Theorem 4.15). The remaining question is what happens if only $\vee$ (but not $\Box$) is allowed. Unfortunately this case has to remain open for now.

4.2.2 BOUNDED ARITY FRAGMENTS

We will now show that $\mathcal{MDL}_k(\vee, \neg, =)$-MC is in P for all $k \geqslant 0$. To prove this statement we will decompose it into two smaller propositions.

First we show that even the whole $\mathcal{MDL}(\vee,\neg,=)$ fragment with unrestricted $=(\cdot)$ atoms is in P as long as it is guaranteed that in every input formula at least a specific number of dependence atoms – depending on the size of the Kripke structure – occur.

We will need the following lemma stating that a dependence atom is always satisfied by a team containing at least half of all the worlds.

Lemma 4.18. *Let $W = (S, R, \pi)$ be a Kripke structure, $\phi := =(p_1, \ldots, p_n, q)$ ($n \geqslant 0$) an atomic formula and $T \subseteq S$ an arbitrary team. Then there is a set $T' \subseteq T$ such that $|T'| \geqslant \frac{|T|}{2}$ and $T' \models \phi$.*

Proof. Let $T_0 := \{s \in T \mid q \notin \pi(s)\}$ and $T_1 := \{s \in T \mid q \in \pi(s)\}$. Then $T_0 \cup T_1 = T$ and $T_0 \cap T_1 = \emptyset$. Therefore there is an $i \in \{1, 2\}$ such that $|T_i| \geqslant \frac{|T|}{2}$. Let $T' := T_i$. Since q is either labeled in every state of T' or in no one, it holds that $W, T' \models \phi$. ■

We will now formalize a notion of "many dependence atoms in a formula".

Definition 4.19. For $\phi \in \mathcal{MDL}$ let $\sigma(\phi)$ be the number of positive dependence atoms in ϕ. Let $\ell\colon \mathbb{N} \to \mathbb{R}$ be an arbitrary function and $\star \in \{<, \leqslant, >, \geqslant, =\}$. Then $\mathcal{MDL}(M)$-MC$_{\star\,\ell(n)}$ (resp. $\mathcal{MDL}_k(M)$-MC$_{\star\ell(n)}$) is the problem $\mathcal{MDL}(M)$-MC (resp. $\mathcal{MDL}_k(M)$-MC) restricted to inputs $(W = (S, R, \pi), T, \phi)$ that satisfy the condition $\sigma(\phi) \star \ell(|S|)$. ┘

If we only allow $\vee$ and we are guaranteed that there are many dependence atoms in each input formula then model checking becomes trivial – even for the case of unbounded dependence atoms.

Proposition 4.20. *Let $M \subseteq \{\vee, \neg, =\}$. Then $\mathcal{MDL}(M)$-MC$_{>\log_2(n)}$ is trivial, i. e. for all Kripke structures $W = (S, R, \pi)$ and all $\phi \in \mathcal{MDL}(M)$ such that the number of positive dependence atoms in ϕ is greater than $\log_2(|S|)$ it holds for all $T \subseteq S$ that $W, T \models \phi$.*

Proof. Let $W = (S, R, \pi)$, $\phi \in \mathcal{MDL}(M)$, $T \subseteq S$ be an arbitrary instance with $\ell > \log_2(|S|)$ positive dependence atoms in ϕ. Then it follows that

$$\phi = \bigvee_{i=1}^{\ell} \underbrace{=(p_{j_{i,1}}, \ldots, p_{j_{i,k_i}})}_{\psi_i} \vee \bigvee_i l_i,$$

where each l_i is either a (possibly negated) atomic proposition or a negated dependence atom.

Claim 1. *For all $k \in \{0,\dots,\ell\}$ there is a set $T_k \subseteq T$ such that $W, T_k \models \bigvee_{i=1}^{k} \psi_i$ and $|T\backslash T_k| < 2^{\ell-k}$.*

The main proposition follows immediately from case $k = \ell$ of this claim: From $|T\backslash T_\ell| < 2^{\ell-\ell} = 1$ follows that $T = T_\ell$ and from $W, T_\ell \models \bigvee_{i=1}^{\ell} \psi_i$ follows that $W, T \models \phi$.

Proof of Claim 1 (inductive). For $k = 0$ we can choose $T_k := \varnothing$. For the inductive step let the claim be true for all $k' < k$. By Lemma 4.18 there is a set $T'_k \subseteq T\backslash T_{k-1}$ such that $W, T'_k \models \psi_k$ and $|T'_K| \geqslant \frac{|T\backslash T_{k-1}|}{2}$. Let $T_k := T_{k-1} \cup T'_k$. Since $W, T_{k-1} \models \bigvee_{i=1}^{k-1} \psi_i$ it follows by definition of the semantics of $\vee$ that $W, T_k \models \bigvee_{i=1}^{k} \psi_i$. Furthermore,

$$\begin{array}{rcccl} |T\backslash T_k| & = & |(T\backslash T_{k-1})\backslash T'_k| & = & |T\backslash T_{k-1}| - |T'_k| \\ & \leqslant & |T\backslash T_{k-1}| - \frac{|T\backslash T_{k-1}|}{2} & = & \frac{|T\backslash T_{k-1}|}{2} \\ & < & \frac{2^{\ell-(k-1)}}{2} & = & 2^{\ell-k}. \end{array} \blacktriangleleft$$

■

Note that $\mathcal{MDL}(M)$-$\mathrm{MC}_{>\log_2(n)}$ is only trivial, i. e. all instance structures satisfy all instance formulas, if we assume that only valid instances, i. e. where the number of dependence atoms is guaranteed to be large enough, are given as input. However, if we have to verify this number the problem clearly remains in P.

Now we consider the case in which we have very few dependence atoms (which have bounded arity) in each formula. We use the fact that there are only a few dependence atoms by searching through all possible determining functions for the dependence atoms. Note that in this case we do not need to restrict the set of allowed $\mathcal{MDL}$ operators as we have done above.

Proposition 4.21. *Let $k \geqslant 0$. Then $\mathcal{MDL}_k$-$\mathrm{MC}_{\leqslant\log_2(n)}$ is in* P.

Proof. From the semantics of $=(\cdot)$ it follows that $=(p_1,\dots,p_k,p)$ is equivalent to

$$\exists f\, f(p_1,\dots,p_k) \leftrightarrow p \quad := \quad \exists f\, \left((\neg f(p_1,\dots,p_k) \vee p) \wedge (f(p_1,\dots,p_k) \vee \neg p)\right) \tag{4.1}$$

where $f(p_1,\dots,p_k)$ and $\exists f\phi$ – both introduced by Sevenster [Sev09, Section 4.2] – have the following semantics:

$$\begin{array}{lll}
W,T \models \exists f\phi & \text{iff} & \text{there is a Boolean function } f^W \text{ such that} \\
 & & (W,f^W),T \models \phi \\
(W,f^W),T \models f(p_1,\dots,p_k) & \text{iff} & \text{for all } s \in T \text{ and for all } x_1,\dots,x_k \in \{0,1\} \\
 & & \text{with } x_i = 1 \text{ iff } p_i \in \pi(s)\ (i = 1,\dots,k)\text{:} \\
 & & f^W(x_1,\dots,x_k) = 1 \\
(W,f^W),T \models \neg f(p_1,\dots,p_k) & \text{iff} & \text{for all } s \in T \text{ and for all } x_1,\dots,x_k \in \{0,1\} \\
 & & \text{with } x_i = 1 \text{ iff } p_i \in \pi(s)\ (i = 1,\dots,k)\text{:} \\
 & & f^W(x_1,\dots,x_k) = 0
\end{array}$$

Now let $W = (S,R,\pi)$, $T \subseteq S$ and $\phi \in \mathcal{MDL}_k$ be a problem instance. First, we count the number ℓ of dependence atoms in ϕ. If $\ell > \log_2(|S|)$ we reject the input instance. Otherwise we replace every dependence atom by its translation according to Eq. (4.1) (each time using a new function symbol). Since the dependence atoms in ϕ are at most k-ary we have from the transformation Eq. (4.1) that the introduced function variables $f_1,\dots,f_\ell$ are also at most k-ary. From this it follows that the upper bound for the number of interpretations of each of them is 2^{2^k}. For each possible tuple of interpretations $f_1^W,\dots,f_\ell^W$ for the function variables we obtain an $\mathcal{ML}$ formula ϕ^* by replacing each existential quantifier $\exists f_i$ by a Boolean formula encoding of the interpretation f_i^W (for example by encoding the truth table of f_i with a formula in disjunctive normal form). For each such tuple we model check ϕ^*. That is possible in polynomial time in $|S| + |\phi^*|$ as shown by Clarke et al. [CES86]. Since the encoding of an arbitrary k-ary Boolean function has length at most 2^k and k is constant this is a polynomial in $|S| + |\phi|$.

Furthermore, the number of tuples over which we have to iterate is bounded by

$$\begin{aligned}
\left(2^{2^k}\right)^{\log_2(|S|)} &= 2^{2^k\cdot\log_2(|S|)} \\
&= \left(2^{\log_2(|S|)}\right)^{2^k} \\
&= |S|^{2^k} \qquad \in \quad |S|^{O(1)}.
\end{aligned}$$

■

With Propositions 4.20 and 4.21 we have shown the following theorem.

Theorem 4.22. *Let* $M \subseteq \{\vee,\neg,=\}$, $k \geqslant 0$. *Then* $\mathcal{MDL}_k(M)$-MC *is in* P.

PROOF. Given a Kripke structure $W = (S,R,\pi)$ and a $\mathcal{MDL}_k(\vee,\neg,=)$ formula ϕ the algorithm counts the number m of positive dependence atoms in ϕ.

If $m > \log_2(|S|)$ the input is accepted (because by Proposition 4.20 the formula is always fulfilled in this case). Otherwise the algorithm from the proof of Proposition 4.21 is used. ∎

And there is another case where we can use the exhaustive determining function search.

Theorem 4.23. *Let $M \subseteq \{\Box, \Diamond, \neg, =\}$. Then $\mathcal{MDL}_k(M)$-MC is in P for every $k \geqslant 0$.*

PROOF. Let $\phi \in \mathcal{MDL}_k(M)$. Then there can be at most one dependence atom in ϕ because M only contains unary operators. Therefore we can once again use the algorithm from the proof of Proposition 4.21. ∎

In Theorem 4.14 we saw that $\mathcal{MDL}(\Diamond, =)$-MC is NP-complete. The previous theorem includes $\mathcal{MDL}_k(\Diamond, =)$-MC $\in$ P as a special case. Hence, the question remains which are the minimal supersets M of $\{\Diamond, =\}$ such that $\mathcal{MDL}_k(M)$-MC is NP-complete.

We will now see that adding either $\wedge$ (Theorem 4.24) or $\vee$ (Theorem 4.25) is already enough to get NP-completeness again. But note that in the case of $\vee$ we need $k \geqslant 1$ while for $k = 0$ the question remains open.

Theorem 4.24. *Let $\{\Diamond, \wedge, =\} \subseteq M$. Then $\mathcal{MDL}_k(M)$-MC is NP-complete for every $k \geqslant 0$.*

PROOF. Membership in NP follows from Proposition 4.12. For hardness we once again reduce 3SAT to our problem.

For this purpose let $\phi := \bigwedge_{i=1}^{m} C_i$ be an arbitrary 3CNF formula built from the variables $x_1, \ldots, x_n$. Let W be the Kripke structure (S, R, π) shown in Figure 4.10 and formally defined by

$$\begin{array}{lcl}
S & := & \{c_i \mid i \in \{1, \ldots, m\}\} \cup \{s_{j,j'}, \overline{s}_{j,j'} \mid j, j' \in \{1, \ldots, n\}\} \\
 & & \cup\ \{t_j, \overline{t}_j \mid j \in \{1, \ldots, n\}\} \\
R & := & \{(c_i, s_{1,j}) \mid x_j \in C_i\} \cup \{(c_i, \overline{s}_{1,j}) \mid \overline{x}_j \in C_i\} \\
 & & \cup\ \{(s_{k,j}, s_{k+1,j}) \mid j \in \{1, \ldots, n\}, k \in \{1, \ldots, n-1\}\} \\
 & & \cup\ \{(\overline{s}_{k,j}, \overline{s}_{k+1,j}) \mid j \in \{1, \ldots, n\}, k \in \{1, \ldots, n-1\}\} \\
 & & \cup\ \{(s_{k,j}, t_j), (\overline{s}_{k,j}, \overline{t}_j) \mid j \in \{1, \ldots, n\}, k \in \{1, \ldots, n\}\} \\
 & & \cup\ \{(s_{k,j}, \overline{t}_j), (\overline{s}_{k,j}, t_j) \mid j \in \{1, \ldots, n\}, k \in \{1, \ldots, n\}, j \neq k\} \\
\pi(c_i) & := & \varnothing \\
\pi(s_{j,j'}) & := & \varnothing \\
\pi(\overline{s}_{j,j'}) & := & \varnothing \\
\pi(t_j) & := & \{r_j, p_j\} \\
\pi(\overline{t}_j) & := & \{r_j\}.
\end{array}$$

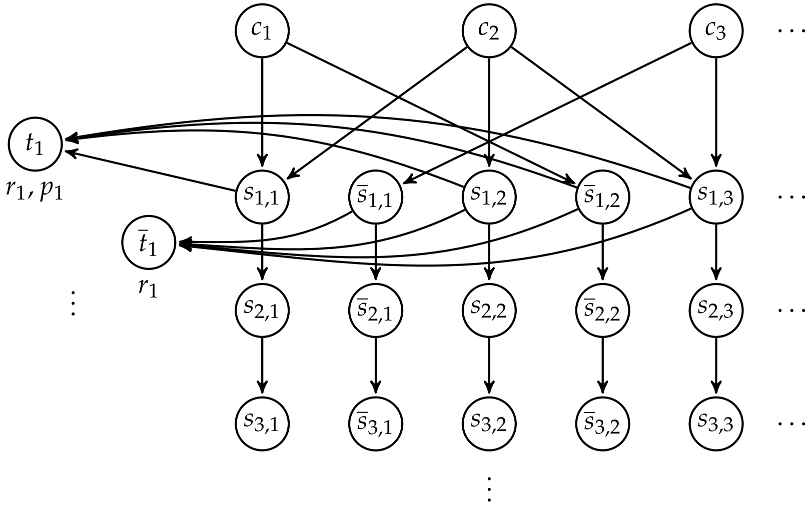

Figure 4.10: Kripke structure corresponding to a 3CNF formula containing the clauses $C_1 = x_1 \vee \neg x_2$, $C_2 = x_1 \vee x_2 \vee x_3$ and $C_3 = \neg x_1 \vee x_3$

And let ψ be the $\mathcal{MDL}(\Diamond, \wedge, =)$ formula

$$\begin{aligned} & \Diamond\left(\bigwedge_{j=1}^{n} \Diamond^{j}(r_j \wedge {=}(p_j))\right) \\ = \quad & \Diamond\big(\Diamond(r_1 \wedge {=}(p_1)) \;\wedge\; \Diamond\Diamond(r_2 \wedge {=}(p_2)) \;\wedge\; \ldots \;\wedge\; \Diamond^{n}(r_n \wedge {=}(p_n))\big). \end{aligned}$$

We again show that $\phi \in$ 3SAT iff $W, \{c_1, \ldots, c_m\} \models \psi$. First assume that $\phi \in$ 3SAT and that θ is a satisfying valuation for the variables in ϕ. Now let

$$s_j := \begin{cases} s_{1,j} & \text{if } x_j \text{ evaluates to true under } \theta \\ \bar{s}_{1,j} & \text{if } x_j \text{ evaluates to false under } \theta \end{cases}$$

for all $j = 1, \ldots, n$. Then it holds that $W, \{s_1, \ldots, s_n\} \models \bigwedge_{j=1}^{n} \Diamond^{j}(r_j \wedge {=}(p_j))$.

Furthermore, since θ satisfies ϕ it holds for all $i = 1, \ldots, m$ that there is a $j_i \in \{1, \ldots, n\}$ such that $(c_i, s_{j_i}) \in R$. Hence,

$$W, \{c_1, \ldots, c_m\} \models \Diamond\left(\bigwedge_{j=1}^{n} \Diamond^{j}(r_j \wedge {=}(p_j))\right).$$

For the reverse direction assume that $W, \{c_1, \dots, c_m\} \models \psi$. Now let $T \subseteq \{s_{1,1}, \bar{s}_{1,1}, s_{1,2}, \dots, \bar{s}_{1,n}\}$ such that $T \models \bigwedge_{j=1}^{n} \Diamond^j (r_j \wedge {=}(p_j))$ and for all $i = 1, \dots, m$ there is a $s \in T$ with $(c_i, s) \in R$.

Since $T \models \Diamond^j (r_j \wedge {=}(p_j))$ there is no $j \in \{1, \dots, n\}$ with $s_{1,j} \in T$ and also $\bar{s}_{1,j} \in T$. Now let θ be the valuation of $x_1, \dots, x_n$ defined by

$$\theta(x_j) := \begin{cases} 1 & \text{if } s_{1,j} \in T \\ 0 & \text{else.} \end{cases}$$

Since for each $i = 1, \dots, m$ there is a $j \in \{1, \dots, n\}$ such that either $(c_i, s_{1,j}) \in R$ and $s_{1,j} \in T$ or $(c_i, \bar{s}_{1,j}) \in R$ and $\bar{s}_{1,j} \in T$ it follows that for each clause C_i of ϕ there is a $j \in \{1, \dots, n\}$ such that x_j satisfies C_i under θ. ∎

Theorem 4.25. *Let $\{\Diamond, \vee, =\} \subseteq M$. Then $\mathcal{MDL}_k(M)$-MC is NP-complete for every $k \geqslant 1$.*

PROOF. As above membership in NP follows from Proposition 4.12 and for hardness we reduce 3SAT to our problem.

For this purpose let $\phi := \bigwedge_{i=1}^{m} C_i$ be an arbitrary 3CNF formula built from the variables $p_1, \dots, p_n$. Let W be the Kripke structure (S, R, π) shown in Figure 4.11 and formally defined by

$$\begin{array}{lcl}
S & := & \{c_{i,j} \mid i \in \{1, \dots, m\}, j \in \{1, \dots, n\}\} \\
 & & \cup \{x_{j,j'} \mid j, j' \in \{1, \dots, n\}, j' \leqslant j\} \\
R & := & \{(c_{i,j}, c_{i,j+1}) \mid i \in \{1, \dots, m\}, j \in \{1, \dots, n-1\}\} \\
 & & \cup \{(x_{j,j'}, x_{j,j'+1}) \mid j \in \{1, \dots, n\}, j' \in \{1, \dots, j-1\}\} \\
\pi(x_{j,j'}) & := & \begin{cases} \{q, p_j\} & \text{iff } j' = j \\ \{q\} & \text{iff } j' < j \end{cases} \\
\pi(c_{i,j}) & := & \begin{cases} \{q\} & \text{iff } p_j, \neg p_j \notin C_i \\ \{p_j\} & \text{iff } p_j \in C_i \\ \emptyset & \text{iff } \neg p_j \in C_i \end{cases}
\end{array}$$

Let ψ be the $\mathcal{MDL}$ formula

$$\begin{array}{rl}
 & \bigvee_{j=1}^{n} \Diamond^{j-1} {=}(q, p_j) \\
= & {=}(q, p_1) \vee \Diamond {=}(q, p_2) \vee \Diamond\Diamond {=}(q, p_3) \vee \dots \vee \Diamond^{n-1} {=}(q, p_n).
\end{array}$$

Once again we show that $\phi \in$ 3SAT iff $W, \{c_{1,1}, \dots, c_{m,1}, x_{1,1}, x_{2,1}, \dots, x_{n,1}\} \models \psi$. Intuitively, the part of the structure comprised of the states $x_{j,j'}$ (pictured in

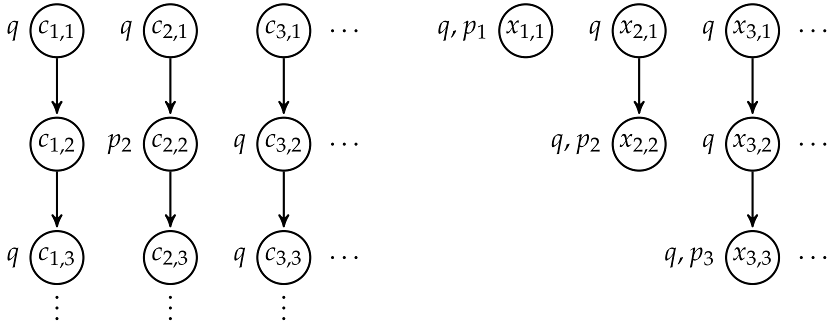

Figure 4.11: Kripke structure corresponding to a 3CNF formula containing the clauses $C_1 = \neg p_2$, $C_2 = p_2 \vee \neg p_3$ and $C_3 = \neg p_1$

the right part of Figure 4.11) together with the subformulas $\Diamond^{j-1}{=}(q, p_j)$ for $j = 1, \ldots, n$ ensures that (for the subteam corresponding to the jth disjunct of ψ) at the jth level (where the levels are counted from 1) p_j is labeled wherever q is labeled. But since in the chains in the $c_{i,j}$ part of the structure it never happens that p_j is labeled if q is labeled it follows that the ith chain cannot belong to the subteam corresponding to the jth disjunct of ψ if q is labeled at its jth level, and, by definition of W, the latter is the case iff neither p_j nor $\neg p_j$ occurs in C_i.

More precisely, first assume that $\phi \in$ 3SAT and that θ is a satisfying valuation for the variables in ϕ. Now let $P_j := \{c_{i,1} \mid C_i \text{ is satisfied by } p_j \text{ under } \theta\}$ for all $j = 1, \ldots, n$. Then it follows that $\bigcup_{j=1}^{n} P_j = \{c_{1,1}, \ldots, c_{m,1}\}$ and that

$$W, P_j \models \Diamond^{j-1}(\neg q \wedge {=}(p_j))$$

for all $j = 1, \ldots, n$. Additionally, it holds that $W, \{x_{j,1}\} \models \Diamond^{j-1}(q \wedge {=}(p_j))$ for $j = 1, \ldots, n$.

Together it follows that $W, P_j \cup \{x_{j,1}\} \models \Diamond^{j-1}{=}(q, p_j)$ for all $j = 1, \ldots, n$. This implies

$$W, \bigcup_{j=1}^{n}(P_j \cup \{x_{j,1}\}) \models \bigvee_{j=1}^{n} \Diamond^{j-1}{=}(q, p_j)$$

which is equivalent to

$$W, \{c_{1,1}, \ldots, c_{m,1}, x_{1,1}, x_{2,1}, \ldots, x_{n,1}\} \models \psi.$$

For the reverse direction assume that $W, T \models \psi$ with $T := \{c_{1,1}, \dots, c_{m,1}, x_{1,1}, x_{2,1}, \dots, x_{n,1}\}$. Let $T_1, \dots, T_n$ be subsets of T with $T_1 \cup \dots \cup T_n = T$ such that for all $j \in \{1, \dots, n\}$ it holds that $T_j \models \Diamond^{j-1}{=}(q, p_j)$. Then it follows that $x_{1,1} \in T_1$ since the chain starting in $x_{1,1}$ consists of only one state. From $\pi(x_{1,1}) = \{q, p_1\}$ and $\pi(x_{2,1}) = \{q\}$ it follows that $x_{2,1} \notin T_1$ and hence (again because of the length of the chain) $x_{2,1} \in T_2$. Inductively, it follows that $x_{j,1} \in T_j$ for all $j = 1, \dots, n$.

Now, it follows from $x_{j,1} \in T_j$ that for all $i \in \{1, \dots, m\}$ with $c_{i,1} \in T_j$: $q \notin \pi(c_{i,j})$ (because $q, p_j \in \pi(x_{j,j}, p_j \notin \pi(x_{i,j}))$. Since $T_j \models \Diamond^{j-1}{=}(q, p_j)$, it then holds that $T_j \backslash \{x_{j,1}\} \models \Diamond^{j-1}(\neg q \wedge {=}(p_j))$.

Now let θ be the valuation of $p_1, \dots, p_n$ defined by

$$\theta(p_j) := \begin{cases} 1 & \text{if } T_j \backslash \{x_{j,1}\} \models \Diamond^{j-1}(\neg q \wedge p_j) \\ 0 & \text{if } T_j \backslash \{x_{j,1}\} \models \Diamond^{j-1}(\neg q \wedge \neg p_j) \end{cases}.$$

Since for each $i = 1, \dots, m$ there is a $j \in \{1, \dots, n\}$ such that $c_{i,1} \in T_j$ it follows that for each clause C_i of ϕ there is a $j \in \{1, \dots, n\}$ such that p_j satisfies C_i under θ. ■

4.2.3 CLASSICAL DISJUNCTION

Finally, we investigate some remaining fragments which allow the classical disjunction operator. Therefore we first show that classical disjunction can substitute zero-ary dependence atoms.

Lemma 4.26. *Let* $=, \ovee \notin M$. *Then*

$$\mathcal{MDL}_0(M \cup \{=\})\text{-MC} \leqslant^{\mathsf{P}}_{\mathrm{m}} \mathcal{MDL}(M \cup \{\ovee\})\text{-MC}.$$

PROOF. Follows immediately from Lemma 3.16b and Lemma 4.11. ■

The following surprising result shows that both kinds of disjunctions together are already enough to get NP-completeness.

Theorem 4.27. *Let* $\{\vee, \ovee\} \subseteq M$. *Then* $\mathcal{MDL}_k(M)$-MC *is* NP-*complete for every* $k \geqslant 0$.

PROOF. As above membership in NP follows from Proposition 4.12 and for hardness we reduce 3SAT to $\mathcal{MDL}_k(\vee, \ovee)$-MC – using a construction that bears some similarities with the one used in the proof of Theorem 4.25.

For this purpose let $\phi := \bigwedge_{i=1}^{m} C_i$ be an arbitrary 3CNF formula built from the variables $p_1, \ldots, p_n$. Let W be the Kripke structure (S, R, π) shown in Figure 4.12 and formally defined by

$$\begin{array}{lcl} S & := & \{c_i \mid i \in \{1, \ldots, m\}\} \\ R & := & \varnothing \\ \pi(c_i) & := & \{p_j \mid p_j \in C_i\} \cup \{q_j \mid \neg p_j \in C_i\}. \end{array}$$

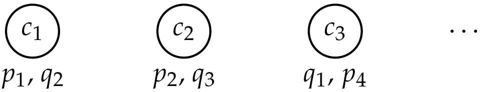

Figure 4.12: Kripke structure corresponding to a 3CNF formula containing the clauses $C_1 = p_1 \vee \neg p_2$, $C_2 = p_2 \vee \neg p_3$ and $C_3 = \neg p_1 \vee p_4$

Let ψ be the $\mathcal{MDL}$ formula

$$\bigvee_{j=1}^{n} (p_j \ovee q_j).$$

Once again we show that $\phi \in$ 3SAT iff $W, \{c_1, \ldots, c_m\} \models \psi$. First assume that $\phi \in$ 3SAT and that θ is a satisfying valuation for ϕ. Now let

$$P_j := \{c_i \mid C_i \text{ is satisfied by } p_j \text{ under } \theta\}$$

for all $j = 1, \ldots, n$. Then it follows that $\bigcup_{j=1}^{n} P_j = \{c_1, \ldots, c_m\}$ and that

$$W, P_j \models p_j \ovee q_j$$

for all $j = 1, \ldots, n$. Together it follows that

$$W, \{c_1, \ldots, c_m\} \models \bigvee_{j=1}^{n} (p_j \ovee q_j).$$

For the reverse direction assume that $W, T \models \psi$ with $T := \{c_1, \ldots, c_m\}$. Let $T_1, \ldots, T_n$ be subsets of T with $T_1 \cup \ldots \cup T_n = T$ such that for all $j \in \{1, \ldots, n\}$ it holds that $T_j \models p_j \ovee q_j$. Now let θ be the valuation of $p_1, \ldots, p_n$ defined by

$$\theta(p_j) := \begin{cases} 1 & \text{if } T_j \models p_j, \\ 0 & \text{if } T_j \models q_j. \end{cases}$$

Since for each $i = 1, \dots, m$ there is a $j \in \{1, \dots, n\}$ such that $c_i \in T_j$ it follows that for each clause C_i of ϕ there is a $j \in \{1, \dots, n\}$ such that p_j satisfies C_i under θ. ■

Now we show that Theorem 4.23 still holds if we additionally allow classical disjunction.

Theorem 4.28. *Let* $M \subseteq \{\Box, \Diamond, \varovee, \neg, =\}$. *Then* $\mathcal{MDL}_k(M)$-MC *is in* P *for every* $k \geqslant 0$.

Proof. Let $\phi \in \mathcal{MDL}(M)$. Because of the distributivity of $\varovee$ with all other $\mathcal{MDL}$ operators (cf. Lemma 4.1a) there is a formula ψ equivalent to ϕ which is of the form

$$\bigovee_{i=1}^{|\phi|} \psi_i$$

with $\psi_i \in \mathcal{MDL}(M \backslash \{\varovee\})$ for all $i \in \{1, \dots, |\phi|\}$. Note that there are only linearly many formulas ψ_i (in contrast to exponentially many in Lemma 4.1a) because ϕ does not contain any binary operators aside from $\varovee$. Further note that ψ can be easily computed from ϕ in polynomial time.

Now it is easy to check for a given structure W and team T whether $W, T \models \psi$ by simply checking whether $W, T \models \psi_i$ (which can be done in polynomial time by Theorem 4.23) consecutively for all $i \in \{1, \dots, |\phi|\}$. ■

4.3 CONCLUSION

Tables 4.1 to 4.4 give a complete overview of our complexity results. Note that all possible combinations of operators are included in each table.

4.3.1 SATISFIABILITY

In this thesis we completely classified the complexity of the satisfiability problem of modal dependence logic for all fragments of the language defined by restricting the modal and propositional operators to a subset of those considered by Väänänen and Sevenster. Our results show a dichotomy for the unbounded arity $=(\cdot)$ operator; either the complexity jumps to NEXP-completeness when introducing $=(\cdot)$ or it does not increase at all – and in the latter case the $=(\cdot)$ operator does not increase the expressiveness of the logic. Intuitively, the NEXP-completeness can be understood as the complexity of guessing Boolean functions of unbounded arity.

An interesting question is whether there are natural fragments of modal dependence logic where adding the dependence operator does not let the complexity of satisfiability testing jump up to NEXP but still increases the expressiveness of the logic. This question can be answered by restricting the arity of the $=(\cdot)$ operator. In this case dependence becomes too weak to increase the complexity beyond PSPACE. However, in the case of poor man's logic, i. e. only disjunctions are fobidden, the complexity increases to Σ_3^{P} when introducing dependence but still it is not as worse as in the case of full modal logic. Intuitively, the complexity drops below NEXP because the Boolean functions which have to be guessed are now of a bounded arity.

4.3.2 MODEL CHECKING

In this thesis we showed that $\mathcal{MDL}$-MC is NP-complete (Theorem 4.13). Furthermore we have systematically analyzed the complexity of model checking for fragments of $\mathcal{MDL}$ defined by restricting the set of modal and propositional operators. It turned out that there are several fragments which stay NP-complete, e. g. the fragment obtained by restricting the set of operators to only $\Box$, $\vee$ and $=$ (Theorem 4.15) or only $\Diamond$ and $=$ (Theorem 4.14). Intuitively, in the former case the NP-hardness arises from existentially guessing partitions of teams while evaluating disjunctions and in the latter from existentially guessing successor teams while evaluating $\Diamond$ operators. Consequently, if we allow all operators except $\Diamond$ and $\vee$ the complexity drops to P (Theorem 4.17).

For the fragment only containing $\vee$ and $=(\cdot)$ on the other hand we were not able to determine whether its model checking problem is tractable. Our inability to prove either NP-hardness or containment in P led us to restrict the arity of the dependence atoms. For the aforementioned fragment the complexity drops to P in the case of bounded arity (Theorem 4.22). Furthermore, some of the cases which are known to be NP-complete for the unbounded case drop to P in the bounded arity case as well (Theorem 4.28) while others remain NP-complete but require a new proof technique (Theorems 4.24 and 4.25). Most noteworthy in this context are probably the results concerning the $\Diamond$ operator. With unbounded dependence atoms this operator alone suffices to get NP-completeness whereas with bounded dependence atoms it needs the additional expressiveness of either $\wedge$ or $\vee$ to reach NP-hardness.

Considering the classical disjunction operator $\varovee$, we showed that the complexity of $\mathcal{MDL}_k(M \cup \{=\})$-MC is never higher than the complexity of $\mathcal{MDL}_k(M \cup \{\varovee\})$-MC, i. e. $\varovee$ is at least as bad as $=(\cdot)$ with respect to the complexity of model-checking (in contrast to the complexity of satisfiability; cf. Table 4.2). And in the case where only $\vee$ is allowed we even have a higher complexity with $\ovee$ (Theorem 4.27) than with $=$ (Theorem 4.22). The case of $\mathcal{MDL}(\vee, \ovee)$-MC is also our probably most surprising result since the nondeterminism of the $\vee$ operator turned out to be powerful enough to lead to NP-completeness although neither conjunction nor dependence atoms (which also, in a sense, contain a kind of "semi-atomic conjunction") are allowed.

Interestingly, in none of our reductions to show NP-hardness the $\mathcal{MDL}$ formula depends on anything else but the number of propositional variables of the input 3CNF formula. The structure of the input formula is always encoded by the Kripke structure alone. So it might seem that even for a fully fixed formula the model checking problem could still be hard. This, however, cannot be the case since, by Proposition 4.21, model checking for a fixed formula is always in P.

Another open question, apart from the unclassified unbounded arity case, is related to a case with bounded arity dependence atoms. In Theorem 4.25 we were only able to prove NP-hardness for arity at least one and it is not known what happens in the case where the arity is zero. Additionally, it might be interesting to determine the exact complexity for the cases which are in P since we have not shown any lower bounds in these cases so far.

4.3.3 OPEN PROBLEMS

In a number of precursor papers, e. g. [Lew79] on propositional logic or [HSS10] on modal logic, not only subsets of the classical operators $\{\Box, \Diamond, \wedge, \vee, \neg\}$ were considered but also propositional connectives given by arbitrary Boolean functions. Contrary to classical propositional or modal logic, however, the semantics of such generalized formulas in dependence logic is not clear a priori – for instance, how should exclusive-or be defined in dependence logic? Even for simple implication there seem to be several reasonable definitions, cf. Section 1.5 and [AV09].

A further possibly interesting restriction of dependence logic might be to restrict the type of functional dependence beyond simply restricting the arity. Right now, dependence just means that there is some function whatsoever that determines the value of a variable from the given values of certain other variables. Also here it might be interesting to restrict the function to be taken from a fixed class in Post's lattice, e. g. to be monotone or self-dual.

Finally, it seems natural to investigate the possibility of enriching classical temporal logics such as $\mathcal{LTL}$, $\mathcal{CTL}$ or $\mathcal{CTL}^*$ with dependence as some of them are extensions of classical modal logic. The questions here are of the same kind as for $\mathcal{MDL}$: expressivity, complexity, fragments (cf. [Mei11] for a systematic study of several classical temporal logics with respect to the complexity of the satisfiability and the model checking problem for fragments).

CHAPTER 5

MODAL INTUITIONISTIC DEPENDENCE LOGIC

5.1 MODEL CHECKING

In this section we study the complexity of model checking for fragments of $\mathcal{MIDL}$, i. e. we extend the results from Section 4.2.

For this purpose first note that Boolean constants as well as negation do not influence the complexity of the model checking problem for $\mathcal{MIDL}$, i. e. Lemma 4.11 holds for $\mathcal{MIDL}$ as well as for $\mathcal{MDL}$.

We begin by stating a PSPACE algorithm for $\mathcal{MIDL}$-MC.

Theorem 5.1. *$\mathcal{MIDL}$-MC is in* PSPACE.

PROOF. We state an AP algorithm to prove the theorem.

Algorithm 5.1: check($K = (S, R, \pi)$,ϕ,T)

```
case $\phi$
when $\phi = \top, \bot, p, \neg p, =(p_1, \ldots, p_n), \psi \vee \chi, \psi \circledvee \chi, \psi \wedge \chi, \Box\psi, \Diamond\psi$
  proceed according to Algorithm 4.2 (guessing steps are existential guessing steps)
when $\phi = \psi \rightarrow \chi$
  universally guess a set of states $T' \subseteq T$
  if not check($K$, $\psi$, $T'$) or check($K$, $\chi$, $T'$)
    return true
  return false
```

Most of the cases in the algorithm are deterministic. Only the cases $\phi = \psi \vee \chi$ and $\phi = \Diamond\psi$ include non-deterministic existential branching and the case $\phi = \psi \rightarrow \chi$ includes non-deterministic universal branching. Altogether, the algorithm can be implemented on an alternating Turing machine running in polynomial time or – equivalently (cf. Definition 2.14 and [CKS81]) – on a deterministic machine using polynomial space. ∎

If we forbid $\vee$ and $\Diamond$ the complexity of the above algorithm drops to coNP.

Corollary 5.2. *$\mathcal{MIDL}(\Box, \wedge, \circledvee, \neg, \rightarrow, =)$-MC is in* coNP*. In particular, $\mathcal{PIDL}$-MC is in* coNP*.*

Proof. In Algorithm 5.1, existential guessing only applies to the cases $\phi = \psi \vee \chi$ and $\phi = \Diamond\psi$. ■

If neither $=(\cdot)$ nor $\circledvee$ are allowed in the logic the model checking problem can even be decided in deterministic polynomial time.

Theorem 5.3. *$\mathcal{MIDL}(\Box, \Diamond, \wedge, \vee, \neg, \rightarrow)$-MC is in* P*.*

Proof. Let ϕ be an arbitrary $\mathcal{MIDL}(\Box, \Diamond, \wedge, \vee, \neg, \rightarrow)$ formula. Starting from the innermost intuitionistic implication $\rightarrow$, by applying Lemma 3.19c, we may eliminate all the connectives $\rightarrow$ in ϕ and obtain an equivalent $\mathcal{ML}$ formula ϕ^*.

The translation from ϕ to ϕ^* can clearly be done in polynomial time and, by [CES86], $\mathcal{ML}$-MC is in P. Hence, $\mathcal{MIDL}(\Box, \Diamond, \wedge, \vee, \neg, \rightarrow)$-MC is in P as well. ■

In the remaining part of this section we provide hardness proofs for model checking problems for various sublogics of $\mathcal{MIDL}$. We first consider the sublogic without $\Diamond$ and $\vee$.

Theorem 5.4. *$\mathcal{PIDL}(\wedge, \circledvee, \rightarrow)$-MC is* coNP*-hard.*

Proof. We give a polynomial-time reduction from

$$\textsc{Taut} := \{\phi \in \mathcal{CL} \mid \phi \text{ is a tautology}\}$$

to $\mathcal{PIDL}$-MC $= \mathcal{PIDL}(\wedge, \circledvee, \neg, \rightarrow, =)$-MC, which implies the desired result since

$$\begin{aligned} \mathcal{PIDL}(\wedge, \circledvee, \neg, \rightarrow, =)\text{-MC} &\equiv^{\mathrm{P}}_{\mathrm{m}} \mathcal{PIDL}(\wedge, \circledvee, \neg, \rightarrow)\text{-MC} \\ &\equiv^{\mathrm{P}}_{\mathrm{m}} \mathcal{PIDL}(\wedge, \circledvee, \rightarrow)\text{-MC}, \end{aligned}$$

by Lemma 3.19 and Lemma 4.11.

For this purpose let ϕ be an arbitrary propositional formula – w. l. o. g. in negation normal form – and let $\mathrm{Var}(\phi) = \{p_1, \dots, p_n\}$. Let $K = (S, R, \pi)$ be the Kripke structure shown in Figure 5.1 and formally defined by

$$\begin{aligned} S &:= \{s_1, \dots, s_n, \overline{s_1}, \dots, \overline{s_n}\}, \\ R &:= \emptyset, \\ \pi(s_i) &:= \{r_i, p_i\}, \\ \pi(\overline{s_i}) &:= \{r_i\}. \end{aligned}$$

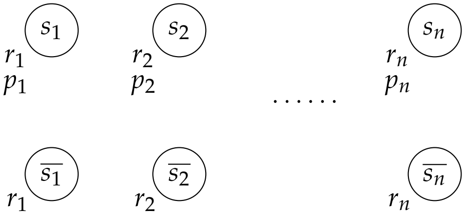

Figure 5.1: Kripke structure in the proof of Theorem 5.4

Finally, let $\psi \in \mathcal{PIDL}$ be defined by

$$\psi \; := \; \alpha_n \rightarrow \phi^{\rightarrow},$$

with

$$\alpha_n := \bigwedge_{i=1}^{n} (r_i \rightarrow {=}(p_i))$$

and $\phi^{\rightarrow}$ defined by the following inductive translation:

$$\begin{aligned} p_i^{\rightarrow} &:= r_i \rightarrow p_i, \\ (\neg p_i)^{\rightarrow} &:= r_i \rightarrow \neg p_i, \\ (\phi \wedge \psi)^{\rightarrow} &:= \phi^{\rightarrow} \wedge \psi^{\rightarrow}, \\ (\phi \vee \psi)^{\rightarrow} &:= \phi^{\rightarrow} \otimes \psi^{\rightarrow}. \end{aligned}$$

Now we will show that $\phi \in$ TAUT iff $K, S \models \psi$.

Suppose $\phi \in$ TAUT. Let $T \subseteq S$ be an arbitrary team such that $K, T \models \alpha_n$. Then there is a $T' \supseteq T$ such that for all $1 \leqslant i \leqslant n$ exactly one of the states s_i and $\overline{s_i}$ is in T'. Now let σ be the truth assignment defined by

$$\sigma(p_i) \; := \; \begin{cases} \top & \text{if } s_i \in T', \\ \bot & \text{if } \overline{s_i} \in T'. \end{cases}$$

Claim 1. *For all subformulas χ of ϕ it holds that σ satisfies χ iff $K, T' \models \chi^{\rightarrow}$.*

PROOF OF CLAIM 1 (INDUCTIVE). Case $\chi = p_i$: First suppose $\sigma(p_i) = \top$. Then for all teams $T'' \subseteq T'$ with $K, T'' \models r_i$ it holds that $T'' \subseteq \{s_i, \overline{s_i}\}$. Furthermore, by definition of T', $T' \cap \{s_i, \overline{s_i}\} = \{s_i\}$. Hence, $T'' \subseteq \{s_i\}$ and $K, T'' \models p_i$. Since T'' was chosen arbitrarily this implies $K, T' \models r_i \rightarrow p_i$. Conversely suppose that $\sigma(p_i) = \bot$. Then $T' \cap \{s_i, \overline{s_i}\} = \{\overline{s_i}\}$ and therefore $T' \not\models r_i \rightarrow p_i$.

Case $\chi = \neg p_i$: Analogous to $\chi = p_i$.

Case $\chi = \tau \vee \theta$: σ satisfies χ

iff σ satisfies τ or σ satisfies θ

iff, by induction hypothesis, $K, T' \models \tau^{\rightarrow}$ or $K, T' \models \theta^{\rightarrow}$

iff, by the semantics of $\ovee$, $K, T' \models \tau^{\rightarrow} \ovee \theta^{\rightarrow}$.

Case $\chi = \tau \wedge \theta$: Analogous to $\chi = \tau \vee \theta$. ◂

Since $\phi \in$ TAUT, it holds that σ satisfies ϕ. By Claim 1 it follows that $K, T' \models \phi^{\rightarrow}$ and, by the downward closure property (Proposition 3.14), $K, T \models \phi^{\rightarrow}$. Since T was chosen arbitrarily with $K, T \models \alpha_n$, this implies $K, S \models \psi$.

Conversely suppose that $K, S \models \psi$ and let σ be an arbitrary truth assignment for $p_1, \ldots, p_n$. Let $T := \{s_i \mid \sigma(p_i) = \top\} \cup \{\overline{s_i} \mid \sigma(p_i) = \bot\}$. Then, obviously, $K, T \models \alpha_n$, thus $K, T \models \phi^{\rightarrow}$ and, by Claim 1, σ satisfies ϕ. Since σ was chosen arbitrarily, $\phi \in$ TAUT. ■

Theorem 5.5. *$\mathcal{PIDL}$-MC is coNP-complete. Furthermore, $\mathcal{MIDL}(M)$-MC is coNP-complete for all $\{\wedge, \ovee, \rightarrow\} \subseteq M \subseteq \{\Box, \wedge, \ovee, \neg, \rightarrow, =\}$.*

PROOF. Follows directly from Corollary 5.2 and Theorem 5.4. ■

Next, we analyze the complexity of model checking for fragments of $\mathcal{MIDL}$ containing $\vee$ and $\rightarrow$.

Theorem 5.6. *Let $\{\wedge, \vee, \rightarrow, =\} \subseteq M$. Then $\mathcal{MIDL}(M)$-MC is PSPACE-complete.*[1]

PROOF. The upper bound follows from Theorem 5.1. For the lower bound we give a reduction from 3CNF-QBF, which is well-known to be PSPACE-complete. Let $\psi = \forall x_1 \exists x_2 \ldots \forall x_{n-1} \exists x_n\, \phi$ be a 3CNF-QBF instance with $\phi = C_1 \wedge \cdots \wedge C_m$ and

$$C_j = \alpha_{j0} \vee \alpha_{j1} \vee \alpha_{j2} \quad (1 \leqslant j \leqslant m)$$

for, w. l. o. g. , distinct $\alpha_{j0}, \alpha_{j1}, \alpha_{j2}$. We further assume w. l. o. g. that n is even. Then the correspoding $\mathcal{MIDL}(\wedge, \vee, \rightarrow, =)$-MC instance is defined as $(K = (S, R, \pi), S, \theta)$, where

- $S := \{s_1, \ldots, s_n, \overline{s_1}, \ldots, \overline{s_n}\}$,
- $R := \emptyset$,
- PROP $:= \{r_1, \ldots, r_n, p_1, \ldots, p_n, c_1, \ldots, c_m, c_{10}, \ldots, c_{m0}, c_{11}, \ldots, c_{m1}, c_{12}, \ldots, c_{m2}\}$

---

[1] Note that $\mathcal{MIDL}(\wedge, \vee, \neg, \rightarrow, =)$ is a variation of $\mathcal{PIDL}$ where $\ovee$ has been replaced by $\vee$.

- $$\begin{aligned}\pi(s_i) = \quad \{r_i, p_i\} \cup \quad & \{c_j, c_{j0} \mid \alpha_{j0} = x_i,\ 1 \leqslant j \leqslant m\} \\ \cup \quad & \{c_j, c_{j1} \mid \alpha_{j1} = x_i,\ 1 \leqslant j \leqslant m\} \\ \cup \quad & \{c_j, c_{j2} \mid \alpha_{j2} = x_i,\ 1 \leqslant j \leqslant m\},\end{aligned}$$
- $$\begin{aligned}\pi(\overline{s_i}) = \quad \{r_i\} \cup \quad & \{c_j, c_{j0} \mid \alpha_{j0} = \neg x_i,\ 1 \leqslant j \leqslant m\} \\ \cup \quad & \{c_j, c_{j1} \mid \alpha_{j1} = \neg x_i,\ 1 \leqslant j \leqslant m\} \\ \cup \quad & \{c_j, c_{j2} \mid \alpha_{j2} = \neg x_i,\ 1 \leqslant j \leqslant m\},\end{aligned}$$
  see Figure 5.2 for an example of the construction of K,
- $\theta := \delta_1$, where

$$\begin{aligned}\delta_{2k-1} &:= (r_{2k-1} \to {=}(p_{2k-1})) \to \delta_{2k} \quad (1 \leqslant k \leqslant n/2), \\ \delta_{2k} &:= (r_{2k} \wedge {=}(p_{2k})) \vee \delta_{2k+1} \quad (1 \leqslant k < n/2), \\ \delta_n &:= (r_n \wedge {=}(p_n)) \vee \phi',\end{aligned}$$

$$\text{i.e. } \theta = \big(r_1 \to {=}(p_1)\big) \to \Big(\big(r_2 \wedge {=}(p_2)\big) \vee \\ \cdots \quad \cdots \quad \cdots \vee \\ \Big(\big(r_{n-1} \to {=}(p_{n-1})\big) \to \Big(\big(r_n \wedge {=}(p_n)\big) \vee \phi'\Big)\Big) \cdots\Big)\Big)\Big),$$

and

$$\phi' := \bigwedge_{j=1}^{m} \Big(c_j \to \Big(\quad \big({=}(c_{j0}) \wedge {=}(c_{j1}) \wedge {=}(c_{j2})\big) \\ \vee \big({=}(c_{j0}) \wedge {=}(c_{j1}) \wedge {=}(c_{j2})\big)\Big)\Big).$$

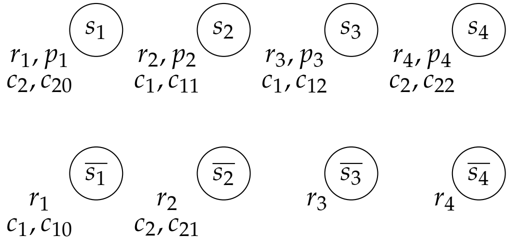

Figure 5.2: Kripke structure corresponding to $\psi = \forall x_1 \exists x_2 \forall x_3 \exists x_4 \big((\neg x_1 \vee x_2 \vee x_3) \wedge (x_1 \vee \neg x_2 \vee x_4)\big)$

We will now show that $\psi \in$ 3CNF-QBF iff $K, S \models \theta$.

The general idea is that the alternating $\rightarrow$ and $\vee$ operators simulate the 3CNF-QBF formula's $\forall$ and $\exists$ quantifiers, respectively. Therefore we start with the team of all states and then for every nesting level i of $\rightarrow$ or $\vee$ we drop one of the states s_i and $\overline{s_i}$. We do this until we arrive at a team that contains exactly one of the states s_i and $\overline{s_i}$ for each $i \in \{1, \ldots, n\}$. This team corresponds to a truth assignment σ for $x_1, \ldots, x_n$ in a natural way and it satisfies ϕ' iff σ satisfies ϕ.

For the universal quantifiers we have that δ_{2k-1} is satisfied in a team T iff δ_{2k} is satisfied in all maximal subteams $T_{2k-1} \subseteq T$ which satisfy $r_{2k-1} \rightarrow {=}(p_{2k-1})$, i. e. all maximal subteams containing only one of the states s_{2k-1} and $\overline{s_{2k-1}}$. For the existential quantifiers δ_{2k} is satisfied in T iff T can be split into T_{2k} and T'_{2k} such that $K, T_{2k} \models \delta_{2k+1}$ and $K, T'_{2k} \models r_{2k} \wedge {=}(p_{2k})$, i. e. δ_{2k+1} has to be satisfied in a team with only one of the states s_{2k} and $\overline{s_{2k}}$ since $T'_{2k} \subseteq \{s_{2k}, \overline{s_{2k}}\}$ and $|T'_{2k}| \leqslant 1$.

More precisely, first suppose that $\psi \in$ 3CNF-QBF. Then for every partial truth assignment $\sigma \restriction \{x_1, x_3, \ldots, x_{n-1}\} \colon \{x_1, x_3, \ldots, x_{n-1}\} \rightarrow \{\top, \bot\}$ there is a complete truth assignment $\sigma \colon \{x_1, x_2, \ldots, x_n\} \rightarrow \{\top, \bot\}$ such that σ satisfies ϕ and $\sigma(x_{2k})$ only depends on $\sigma(x_1), \sigma(x_3), \ldots, \sigma(x_{2k-1})$ (for all $k \in \{1, \ldots, n/2\}$).

We now have to show that

$$K, S \models (r_1 \rightarrow {=}(p_1)) \rightarrow \delta_2.$$

By the downward closure property (Proposition 3.14), it suffices to show that for the maximal teams $T_1 \subseteq S$ such that $K, T_1 \models r_1 \rightarrow {=}(p_1)$, namely the teams $T_1 = S \backslash \{s_1\}$ and $T_1 = S \backslash \{\overline{s_1}\}$, it holds that

$$K, T_1 \models \delta_2, \text{ i. e. } K, T_1 \models (r_2 \wedge {=}(p_2)) \vee \delta_3.$$

Choose the value of $\sigma(x_1)$ according to T_1 by letting

$$\sigma(x_1) := \begin{cases} \top & \text{if } T_1 = S \backslash \{s_1\}, \\ \bot & \text{if } T_1 = S \backslash \{\overline{s_1}\}. \end{cases}$$

Note that $\sigma(x_1)$ is defined as the *complement* of the canonical truth assignment corresponding to T_1 – which was used in the proof of Theorem 5.4. We are going to continue to define the truth assignment as the complement of the canonical one. The reason for this will become clear when we show the connection between ϕ and ϕ' in the end.

Now we split the team T_1 into T_2 and T'_2 according to the value of $\sigma(x_2)$ (which is defined by the above assumption following from $\psi \in$ 3CNF-QBF) as follows:

$$T_2' := \begin{cases} \{s_2\} & \text{if } \sigma(x_2) = \top, \\ \{\overline{s_2}\} & \text{if } \sigma(x_2) = \bot, \end{cases}$$

and $T_2 = T_1 \backslash T_2'$. Clearly, $K, T_2' \models r_2 \wedge {=}(p_2)$ and it suffices to check that $K, T_2 \models \delta_3$.

We know that to show $K, S \models \delta_1$ it is enough to show that for every T_1 (as constructed above) there is a T_2 (as constructed above) such that $K, T_2 \models \delta_3$. By repeating the same arguments and constructions $n/2$ times, it remains to show that $K, T_n \models \phi'$. Now, T_n and σ are interdependently defined by

$$\begin{aligned} \sigma(x_i) &:= \begin{cases} \top & \text{if} \quad T_n \cap \{s_i, \overline{s_i}\} = \{\overline{s_i}\} \\ \bot & \text{if} \quad T_n \cap \{s_i, \overline{s_i}\} = \{s_i\} \end{cases} && \text{for } i \in \{1, 3, \dots, n-1\}, \\ T_n \cap \{s_i, \overline{s_i}\} &:= \begin{cases} \{s_i\} & \text{if} \quad \sigma(x_i) = \bot \\ \{\overline{s_i}\} & \text{if} \quad \sigma(x_i) = \top \end{cases} && \text{for } i \in \{2, 4, \dots, n\}, \end{aligned} \tag{5.1}$$

and σ satisfies ϕ, i. e. for all $j \in \{1, \dots, m\}$ it holds that $\sigma(\alpha_{j0}) = \top$, $\sigma(\alpha_{j1}) = \top$ or $\sigma(\alpha_{j2}) = \top$.

Now let $j \in \{1, \dots, m\}$ be arbitrarily chosen, let, for example, $\alpha_{j0} = \neg x_{i_0}$, $\alpha_{j1} = \neg x_{i_1}$, $\alpha_{j2} = x_{i_2}$ (for some $i_0, i_1, i_2 \in \{1, \dots, n\}$) and let w. l. o. g. $\sigma(\alpha_{j1}) = \top$, i. e. $\sigma(x_{i_1}) = \bot$. Let $T' \subseteq T_n$ be arbitrarily chosen such that $K, T' \models c_j$. Then, by construction of K, it holds that $T' \subseteq \{\overline{s_{i_0}}, \overline{s_{i_1}}, s_{i_2}\}$ and, by Eq. (5.1) and $T' \subseteq T_n$, we further obtain that $\overline{s_{i_1}} \notin T'$. Hence, $T' \subseteq \{\overline{s_{i_0}}, s_{i_2}\}$, i. e. $|T'| \leqslant 2$, and therefore

$$K, T' \models \big({=}(c_{j0}) \wedge {=}(c_{j1}) \wedge {=}(c_{j2})\big) \vee \big({=}(c_{j0}) \wedge {=}(c_{j1}) \wedge {=}(c_{j2})\big).$$

Since j was chosen arbitrarily it follows that $K, T_n \models \phi'$.

Conversely, suppose $K, S \models \theta$. By reversing the arguments and constructions from above and again repeating them $n/2$ times, we arrive at the interdependence from Eq. (5.1) again. The crucial observation is that when evaluating $(r_{2k-1} \to {=}(p_{2k-1})) \to \delta_{2k}$ we only need to consider the maximal teams satisfying $r_{2k-1} \to {=}(p_{2k-1})$ and there are exactly two of those, one without s_{2k-1} and the other one without $\overline{s_{2k-1}}$. And when evaluating $(r_{2k} \wedge {=}(p_{2k})) \vee \delta_{2k+1}$ we have to consider only the complements of the maximal teams satisfying $r_{2k} \wedge {=}(p_{2k})$ and again there are exactly two, one without s_{2k} and the other one without $\overline{s_{2k}}$.

It remains to show that σ satisfies ϕ. That is to show that σ satisfies $\alpha_{j_0} \vee \alpha_{j_1} \vee \alpha_{j_2}$ for an arbitrarily chosen $j \in \{1, \dots, m\}$. Suppose, for example,

$$\alpha_{j_0} = x_{i_0}, \ \alpha_{j_1} = x_{i_1} \text{ and } \alpha_{j_2} = \neg x_{i_2}.$$

Now let $T' \subseteq T_n$ be the maximal team such that $K, T' \models c_j$. Then, by construction of K, we have that $T' \subseteq \{s_{i_0}, s_{i_1}, \overline{s_{i_2}}\}$. Since $K, T_n \models \phi'$ it holds that

$$K, T' \models \big(=(c_{j0}) \wedge =(c_{j1}) \wedge =(c_{j2})\big) \vee \big(=(c_{j0}) \wedge =(c_{j1}) \wedge =(c_{j2})\big)$$

and thus, by construction of K, it follows that $|T'| \leqslant 2$. Say $s_{i_1} \notin T'$, then, by maximality of T', we obtain that $s_{i_1} \notin T_n$ which, by Eq. (5.1), means that $\sigma(x_{i_1}) = \top$, i. e. $\sigma(\alpha_{j_1}) = \top$. Hence, as j was chosen arbitrarily, it follows that σ satisfies ϕ. ■

Finally, we study the model checking problem for sublogics of $\mathcal{MIDL}$ including $\Diamond$ and $\ovee$.

Theorem 5.7. *Let* $\{\Diamond, \wedge, \ovee, \rightarrow\} \subseteq M$. *Then* $\mathcal{MIDL}(M)$-MC *is* PSPACE-*complete.*

PROOF. The upper bound again follows from Theorem 5.1. For the lower bound we give a polynomial-time reduction from QBF to $\mathcal{MIDL}(\Diamond, \wedge, \ovee, \neg, \rightarrow, =)$-MC, which implies the desired result since

$$\begin{aligned} \mathcal{MIDL}(\Diamond, \wedge, \ovee, \neg, \rightarrow, =)\text{-MC} &\equiv^{\mathrm{P}}_{\mathrm{m}} \mathcal{MIDL}(\Diamond, \wedge, \ovee, \neg, \rightarrow)\text{-MC} \\ &\equiv^{\mathrm{P}}_{\mathrm{m}} \mathcal{MIDL}(\Diamond, \wedge, \ovee, \rightarrow)\text{-MC}, \end{aligned}$$

by Lemma 3.19 and Lemma 4.11.

Let $\psi = \forall x_1 \exists x_2 \ldots \forall x_{n-1} \exists x_n \, \phi$ with n even and ϕ quantifier-free. The corresponding $\mathcal{MIDL}(\Diamond, \wedge, \ovee, \neg, \rightarrow, =)$-MC instance is defined as $(K = (S, R, \pi), T, \theta)$ where

- $S := \bigcup\limits_{1 \leqslant i \leqslant n} S_i, \quad R := \bigcup\limits_{1 \leqslant i \leqslant n} R_i$ and for $1 \leqslant i \leqslant n/2$

$$\begin{aligned} S_{2i-1} &:= \{s_{2i-1}, \overline{s_{2i-1}}\} \\ S_{2i} &:= \{s_{2i}, \overline{s_{2i}}\} \cup \{t_i\} \cup \{t_{i1}, \cdots, t_{i(i-1)}\} \\ R_{2i-1} &:= \{(s_{2i-1}, s_{2i-1}), (\overline{s_{2i-1}}, \overline{s_{2i-1}})\} \\ R_{2i} &:= \{(t_i, t_{i1}), (t_{i1}, t_{i2}), \cdots, (t_{i(i-2)}, t_{i(i-1)})\} \\ &\quad \cup \{(t_{i(i-1)}, s_{2i}), (t_{i(i-1)}, \overline{s_{2i}})\} \\ &\quad \cup \{(s_{2i}, s_{2i}), (\overline{s_{2i}}, \overline{s_{2i}})\} \end{aligned}$$

- $\pi(s_j) := \{r_j, p_j\}$,
- $\pi(\overline{s_j}) := \{r_j\}$,

- $\pi(t) := \varnothing$, for $t \notin \{s_j, \overline{s_j} \mid 1 \leqslant j \leqslant n\}$,

  see Figure 5.3 for the construction of K,
- $T := \{s_i, \overline{s_i} \mid 1 \leqslant i \leqslant n,\ i \text{ odd}\} \cup \{t_i \mid 1 \leqslant i \leqslant n/2\}$;
- $\theta = \delta_1$, where

$$\begin{aligned} \delta_{2k-1} &:= (r_{2k-1} \to {=}(p_{2k-1})) \to \delta_{2k} \quad (1 \leqslant k \leqslant n/2), \\ \delta_{2k} &:= \Diamond \delta_{2k+1} \quad (1 \leqslant k < n/2), \\ \delta_n &:= \Diamond \phi^{\to}, \end{aligned}$$

$$\text{i.e. } \theta = \Big((r_1 \to {=}(p_1)) \to \Diamond \quad \cdots \quad \cdots \to \Diamond \Big((r_{n-1} \to {=}(p_{n-1})) \to \Diamond \phi^{\to} \Big) \Big) \ldots \Big) \Big),$$

  and $\phi^{\to}$ is generated from ϕ by the same inductive translation as in the proof of Theorem 5.4.

Analogously to the proofs of Theorem 5.6 and Theorem 5.4 we will show that $\psi \in \mathrm{QBF}$ iff $K, T \models \theta$. The idea, analogous to the proof of Theorem 5.6, is that the alternating $\to$ and $\Diamond$ operators simulate the QBF formula's $\forall$ and $\exists$ quantifiers, respectively. Therefore we start with the team of all states in the beginning of the chains and then for every nesting level i of $\to$ we drop one of the states s_{2i+1} and $\overline{s_{2i+1}}$ while for every nesting level i of $\Diamond$ we simultaneously move forward in the chains and thereby choose one of the states s_{2i} and $\overline{s_{2i}}$. We do this until we arrive at a team that contains exactly one of the states s_i and $\overline{s_i}$ for each $i \in \{1, \ldots, n\}$. This team corresponds to a truth assignment σ for $x_1, \ldots, x_n$ in the canonical way (as in the proof of Theorem 5.4) and it satisfies $\phi^{\to}$ iff σ satisfies ϕ.

Now suppose that $\psi \in \mathrm{QBF}$. Then by applying the same arguments as in the proof of Theorem 5.6 (but with the canonical instead of the complementary mapping between truth assignments and teams) we get a team T_1 and values for $\sigma(x_1)$ and $\sigma(x_2)$. Depending on this we choose $T_2 \in \langle T_1 \rangle$ as follows:

$$T_2 := \begin{cases} R(T_1) \backslash \{\overline{s_2}\} & \text{if } \sigma(x_2) = \top, \\ R(T_1) \backslash \{s_2\} & \text{if } \sigma(x_2) = \bot, \end{cases}$$

Now it suffices to check that $K, T_2 \models \delta_3$. And, again analogous to the proof of Theorem 5.6, by repeating the universal and the existential arguments $n/2$

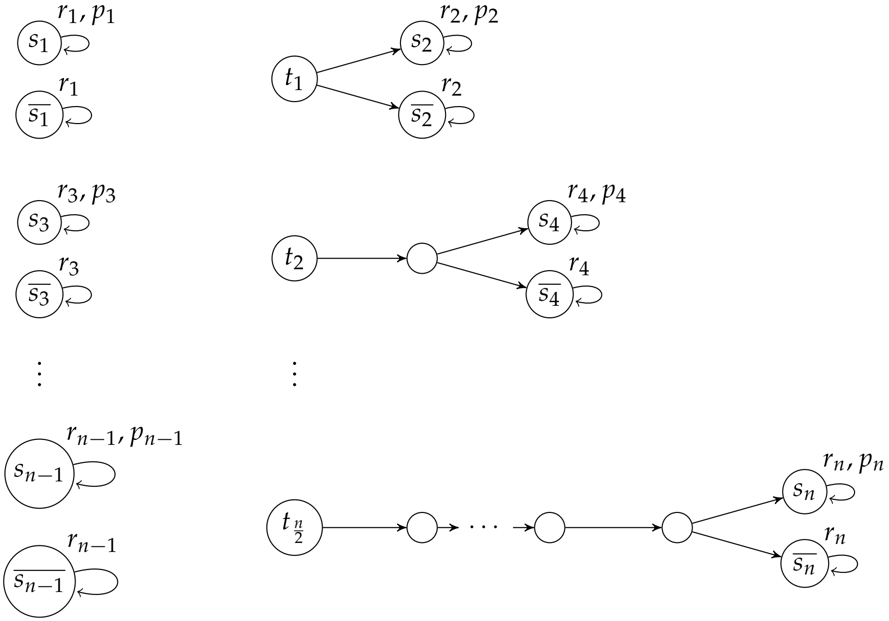

Figure 5.3: Kripke structure in the proof of Theorem 5.7

times, it remains to show that $K, T_n \models \phi^{\rightarrow}$. And, analogous to Eq. (5.1) (except for not taking the complement), T_n and σ are interdependently defined by

$$\begin{aligned} \sigma(x_i) &:= \begin{cases} \top & \text{if} \quad T_n \cap \{s_i, \overline{s_i}\} = \{s_i\} \\ \bot & \text{if} \quad T_n \cap \{s_i, \overline{s_i}\} = \{\overline{s_i}\} \end{cases} && \text{for } i \in \{1, 3, \dots, n-1\}, \\ T_n \cap \{s_i, \overline{s_i}\} &:= \begin{cases} \{s_i\} & \text{if} \quad \sigma(x_i) = \top \\ \{\overline{s_i}\} & \text{if} \quad \sigma(x_i) = \bot \end{cases} && \text{for } i \in \{2, 4, \dots, n\}. \end{aligned} \tag{5.2}$$

Now, by Claim 1 in the proof of Theorem 5.4 (T' there is of the same structure as T_n here and $\phi^{\rightarrow}$ does not contain any modalities), it holds that $K, T_n \models \phi^{\rightarrow}$ since, by assumption, σ satisfies ϕ.

Conversely, suppose that $K, T \models \theta$. As in the proof of Theorem 5.6 we can reverse the above constructions and arrive at the interdependence from Eq. (5.2) again. The crucial point is that when evaluating $\Diamond\delta_{2k+1}$ we only have to consider minimal successor teams.

Now, as above, by Claim 1 in the proof of Theorem 5.4, it holds that σ satisfies ϕ since, by assumption and by the construction of T_n, $K, T_n \models \phi^{\rightarrow}$. ∎

5.2 CONCLUSION

We have shown that model checking for $\mathcal{MIDL}$ in general is PSPACE-complete and that this still holds if we forbid $\Box$ and $=(\cdot)$ together with either $\Diamond$ or $\vee$. For $\mathcal{PIDL}$ (where neither $\Box$, $\Diamond$ nor $\vee$ are allowed) the complexity drops to coNP. All our results are listed in Table 5.1.

Operators								Complexity	Reference/ Method
$\Box$	$\Diamond$	$\wedge$	$\vee$	$\varovee$	$\neg$	$\rightarrow$	$=(\cdot)$

Table 5.1: Classification of complexity for fragments of $\mathcal{MIDL}$-MC
All results are completeness results except for the P cases which are upper bounds.

Note that some cases are missing in Table 5.1, e. g. the one where only conjunction is forbidden, the one where only both disjunctions are forbidden and the one from Theorem 5.7 but with classical disjunction forbidden instead of dependence atoms. Also, the expressiveness and the satisfiability problem of $\mathcal{MIDL}$ need to be studied.

CHAPTER 6

TWO-VARIABLE DEPENDENCE LOGIC

In this chapter we will assume that all first-order vocabularies are purely relational, i. e. they do not contain function or constant symbols. And w. l. o. g. we assume that all relation symbols are at most binary.

6.1 COMPARISON OF $\mathcal{IF}^2$ AND $\mathcal{D}^2$

In this section we show that

$$\mathcal{D}^2 < \mathcal{IF}^2 \leqq \mathcal{D}^3,$$

using results from Sections 6.2 and 6.3 in advance. We also further discuss the expressive powers and other logical properties of $\mathcal{D}^2$ and $\mathcal{IF}^2$.

Lemma 6.1. *For any formula $\phi \in \mathcal{D}^2$ there is a formula $\phi^* \in \mathcal{IF}^2$ such that for all structures $\mathfrak{A}$ and teams X, where $\mathrm{dom}(X) = \{x, y\}$, it holds that*

$$\mathfrak{A} \models_X \phi \quad \textit{iff} \quad \mathfrak{A} \models_X \phi^*.$$

PROOF. The translation $\phi \mapsto \phi^*$ is defined as follows. For first-order literals the translation is the identity, and negations of dependence atoms are translated by $\neg x = x$. The remaining cases are defined as follows:

$$\begin{aligned} =\!(x) &\quad\mapsto\quad \exists y/\{x,y\}(x = y) \\ =\!(x,y) &\quad\mapsto\quad \exists x/\{y\}(x = y) \\ \phi \wedge \psi &\quad\mapsto\quad \phi^* \wedge \psi^* \\ \phi \vee \psi &\quad\mapsto\quad \phi^* \vee \psi^* \\ \exists x\phi &\quad\mapsto\quad \exists x\phi^* \\ \forall x\phi &\quad\mapsto\quad \forall x\phi^* \end{aligned}$$

The claim of the lemma can now be proved using induction on ϕ. The only non-trivial cases are the dependence atoms. We consider the case where ϕ is of the form $=(x, y)$.

Let us assume that $\mathfrak{A} \models_X \phi$. Then there is a function $F\colon A \to A$ such that

$$\text{for all } s \in X : \; s(y) = F(s(x)). \tag{6.1}$$

Define now $F'\colon X \to A$ as follows:

$$F'(s) := F(s(x)). \tag{6.2}$$

F' is $\{y\}$-independent since, if $s(x) = s'(x)$, then

$$F'(s) = F(s(x)) = F(s'(x)) = F'(s').$$

It remains to show that

$$\mathfrak{A} \models_{X(F'/x)} (x = y). \tag{6.3}$$

Let $s \in X(F'/x)$. Then

$$s = s'(F'(s')/x) \text{ for some } s' \in X. \tag{6.4}$$

Now

$$s(x) \overset{(6.4)}{=} F'(s') \overset{(6.2)}{=} F(s'(x)) \overset{(6.1)}{=} s'(y) \overset{(6.4)}{=} s(y).$$

Therefore, Eq. (6.3) holds, and hence also

$$\mathfrak{A} \models_X \exists x/\{y\}(x = y).$$

Suppose then that $\mathfrak{A} \not\models_X \phi$. Then there must be $s, s' \in X$ such that $s(x) = s'(x)$ and $s(y) \neq s'(y)$. We claim now that

$$\mathfrak{A} \not\models_X \exists x/\{y\}(x = y). \tag{6.5}$$

Let $F\colon X \to A$ be an arbitrary $\{y\}$-independent function. Then, by $\{y\}$-independence, $F(s) = F(s')$ and since additionally $s(y) \neq s'(y)$, we have

$$s(F(s)/x)(x) = F(s) \neq s(y) = s(F(s)/x)(y)$$

or

$$s'(F(s')/x)(x) = F(s') \neq s'(y) = s'(F(s')/x)(y).$$

This implies that

$$\mathfrak{A} \not\models_{X(F/x)} (x = y),$$

since $s(F(s)/x)$, $s'(F(s')/x) \in X(F/x)$.

Since F was arbitrary, we may conclude that Eq. (6.5) holds. ∎

Next we show a translation from $\mathcal{IF}^2$ to $\mathcal{D}^3$.

Lemma 6.2. *For any formula $\phi \in \mathcal{IF}^2$ there is a formula $\phi^* \in \mathcal{D}^3$ such that for all structures $\mathfrak{A}$ and teams X, where* $\mathrm{dom}(X) = \{x, y\}$, *it holds that*

$$\mathfrak{A} \models_X \phi \quad \textit{iff} \quad \mathfrak{A} \models_X \phi^*.$$

Proof. The claim follows by the following translation $\phi \mapsto \phi^*$: For atomic and negated atomic formulas the translation is the identity, and for propositional connectives and first-order quantifiers it is defined in the obvious inductive way. The only non-trivial cases are the slashed quantifiers:

$$\begin{array}{rcl} \exists x/\{y\}\psi & \mapsto & \exists z(x = z \wedge \exists x(=(z, x) \wedge \psi^*)), \\ \exists x/\{x\}\psi & \mapsto & \exists x(=(y, x) \wedge \psi^*), \\ \exists x/\{x, y\}\psi & \mapsto & \exists x(=(x) \wedge \psi^*). \end{array}$$

Again, the claim can be proved using induction on ϕ. We consider the case where ϕ is of the form $\exists x/\{y\}\psi$. Assume $\mathfrak{A} \models_X \phi$. Then there is a $\{y\}$-independent function $F\colon X \to A$ such that

$$\mathfrak{A} \models_{X(F/x)} \psi. \tag{6.6}$$

By $\{y\}$-independence, $s(x) = s'(x)$ implies that $F(s) = F(s')$ for all $s, s' \in X$. Our goal is to show that

$$\mathfrak{A} \models_X \exists z(x = z \wedge \exists x(=(z, x) \wedge \psi^*)). \tag{6.7}$$

Now, Eq. (6.7) holds if for $G\colon X \to A$ defined by $G(s) = s(x)$ for all $s \in X$ it holds that

$$\mathfrak{A} \models_{X(G/z)} \exists x(=(z, x) \wedge \psi^*). \tag{6.8}$$

Define $F'\colon X(G/z) \to A$ by $F'(s) = F(s \upharpoonright \{x, y\})$. Now we claim that

$$\mathfrak{A} \models_{X(G/z)(F'/x)} =(z, x) \wedge \psi^*,$$

implying Eq. (6.8) and hence Eq. (6.7).

First we show that

$$\mathfrak{A} \models_{X(G/z)(F'/x)} =(z, x). \tag{6.9}$$

At this point it is helpful to note that every $s \in X(G/z)(F'/x)$ arises from an $s' \in X$ by first copying the value of x to z and then replacing the value of x by

$F(s \upharpoonright \{x,y\})$, i. e. that $s(z) = s'(G(s')/z)(z) = G(s') = s'(x)$ and $s(x) = F(s')$. Now, to show Eq. (6.9), let $s_1, s_2 \in X(G/z)(F'/x)$ with $s_1(z) = s_2(z)$ and let $s'_1, s'_2 \in X$ as above, i. e. s_1 (resp. s_2) arises from s'_1 (resp. s'_2). Then it follows that $s'_1(x) = s'_2(x)$. Hence, by $\{y\}$-independence, $F(s'_1) = F(s'_2)$, implying that $s_1(x) = F(s'_1) = F(s'_2) = s_2(x)$ which proves Eq. (6.9). Let us then show that

$$\mathfrak{A} \models_{X(G/z)(F'/x)} \psi^*. \tag{6.10}$$

Note first that by the definition of the mapping $\phi \mapsto \phi^*$ the variable z cannot appear free in ψ^*. By Proposition 3.7, the satisfaction of any $\mathcal{D}$ formula θ only depends on those variables in a team that appear free in θ, therefore Eq. (6.10) holds iff

$$\mathfrak{A} \models_{X(G/z)(F'/x)\upharpoonright\{x,y\}} \psi^*. \tag{6.11}$$

We have chosen G and F' in such a way that

$$X(G/z)(F'/x) \upharpoonright \{x,y\} = X(F/x),$$

hence Eq. (6.11) now follows from Eq. (6.6) and the induction hypothesis.

We omit the proof of the converse implication which is analogous. ■

For sentences, Lemmas 6.1 and 6.2 now imply the following.

Theorem 6.3. $\mathcal{D}^2 \leqq \mathcal{IF}^2 \leqq \mathcal{D}^3$

PROOF. The claim follows by Lemmas 6.1 and 6.2. First of all, if ϕ is a sentence of $\mathcal{IF}$ or $\mathcal{D}$, then, by Proposition 3.7, for every model $\mathfrak{A}$ and team $X \neq \emptyset$

$$\mathfrak{A} \models_X \phi \text{ iff } \mathfrak{A} \models_{\{\emptyset\}} \phi. \tag{6.12}$$

It is important to note that, even if $\phi \in \mathcal{D}^2$ is a sentence, it may happen that ϕ^* has free variables since variables in W are regarded as free in subformulas of ϕ^* of the form $\exists x/W\psi$. However, this is not a problem. Let Y be the set of all assigments of $\mathfrak{A}$ with the domain $\{x,y\}$. Now

$$\begin{aligned} \mathfrak{A} \models_{\{\emptyset\}} \phi \quad & \text{iff} \quad \mathfrak{A} \models_Y \phi \\ & \text{iff} \quad \mathfrak{A} \models_Y \forall x \forall y \phi \\ & \text{iff} \quad \mathfrak{A} \models_Y \forall x \forall y \phi^* \\ & \text{iff} \quad \mathfrak{A} \models_{\{\emptyset\}} \forall x \forall y \phi^*, \end{aligned}$$

where the first and the last equivalence hold by Eq. (6.12), the second by the semantics of the universal quantifier and the third by Lemma 6.1. An analogous argument can be used to show that for every sentence $\phi \in \mathcal{IF}^2$ there is an equivalent sentence of the logic $\mathcal{D}^3$. ■

6.1.1 EXAMPLES OF PROPERTIES DEFINABLE IN $\mathcal{D}^2$

We now give some examples of definable classes of structures in $\mathcal{D}^2$ (and in $\mathcal{IF}^2$ by Theorem 6.3).

Proposition 6.4. *The following properties can be expressed in* $\mathcal{D}^2$.

a) *For unary relation symbols P and Q, $\mathcal{D}^2$ can express $|P| \leqslant |Q|$. This shows $\mathcal{D}^2 \nleqq \mathcal{FO}$.*

b) *If the vocabulary of $\mathfrak{A}$ contains a constant c, then $\mathcal{D}^2$ can express that A is infinite.*

c) *$|A| \leqslant k$ can be expressed already in $\mathcal{D}^1$.*

PROOF. Let us first consider part a). Define ϕ by

$$\phi := \forall x \exists y ({=}(y, x) \wedge (\neg P(x) \vee Q(y))).$$

Now, $\mathfrak{A} \models \phi$ iff there is an injective function $F\colon A \to A$ with $F[P^{\mathfrak{A}}] \subseteq Q^{\mathfrak{A}}$
iff $|P^{\mathfrak{A}}| \leqslant |Q^{\mathfrak{A}}|$.

For part b), we use the same idea as above. Define ψ by

$$\psi := \forall x \exists y ({=}(y, x) \wedge \neg c = y).$$

Now, $\mathfrak{A} \models \psi$ iff there is an injective function $F\colon A \to A$ with $c^{\mathfrak{A}} \notin F[A]$
iff A is infinite.

Finally, we show how to express the property from part c). Define θ as

$$\forall x (\bigvee_{1 \leqslant i \leqslant k} \chi_i),$$

where χ_i is ${=}(x)$. It is now immediate that $\mathfrak{A} \models \theta$ iff $|A| \leqslant k$. ∎

It is interesting to note that part a) implies that $\mathcal{D}^2$ does not have a zero-one law, since the property $|P| \leqslant |Q|$ has the limit probability $\frac{1}{2}$.

Proposition 6.5. *$\mathcal{D}^2 < \mathcal{IF}^2$. This holds already in the finite.*

PROOF. Almost all $\mathcal{IF}^2$ formulas used in Section 6.2 to prove the undecidability of the (finite) satisfiability problem of $\mathcal{IF}^2$ are in fact $\mathcal{FO}^2$ formulas. The only exception is the formula ϕ_{join} (which is part of the formula ϕ_{grid}, cf. Definition 6.14). Therefore, if ϕ_{join} could be expressed in $\mathcal{D}^2$ then (finite) satisfiability would be as undecidable for $\mathcal{D}^2$ as it is for $\mathcal{IF}^2$. But this is a contradiction to Theorem 6.25 and, hence, the $\mathcal{IF}^2$ formula ϕ_{join} is not definable in $\mathcal{D}^2$. ∎

6.2 SATISFIABILITY IS UNDECIDABLE FOR $\mathcal{IF}^2$

In this section we will use tiling problems, introduced by Wang [Wan61], to show the undecidability of $\mathcal{IF}^2$-SAT as well as $\mathcal{IF}^2$-FINSAT.

Here, a *Wang tile* is a square in which each edge (top, right, bottom, left) is assigned a color. We say that a set of tiles can tile the $\mathbb{N} \times \mathbb{N}$ plane if a tile can be placed on each point $(i, j) \in \mathbb{N} \times \mathbb{N}$ such that the right color of the tile in (i, j) is the same as the left color of the tile in $(i + 1, j)$ and the top color of the tile in (i, j) is the same as the bottom color of the tile in $(i, j + 1)$. Notice that turning and flipping tiles is not allowed.

We then define some specific structures needed later.

Definition 6.6. Let $m, n \in \mathbb{N} \cup \{\infty\}$. Then the model $\mathfrak{G}_{m\times n} := (G, V, H)$ where

- $G = \{0, \ldots, m\} \times \{0, \ldots, n\}$,
- $H = \{((i, j), (i + 1, j)) \in G \times G \mid i < m, j \leqslant n\}$ and
- $V = \{((i, j), (i, j + 1)) \in G \times G \mid i \leqslant m, j < n\}$

is called the *$(m \times n)$-grid*. Instead of $\mathfrak{G}_{\infty\times\infty}$ we sometimes just write $\mathfrak{G}$ and call it the *infinite grid*. The set $\{\mathfrak{G}_{m\times n} \mid m, n \in \mathbb{N}\}$ of all *finite grids* is denoted by FinGrid. ⌟

Definition 6.7. A set of *colors* C is defined to be an arbitrary finite set. The set of all *(Wang) tiles* over C is C^4, i. e. a tile is an ordered list of four colors, interpreted as the colors of the four edges of the tile in the order top, right, bottom and left. A tile $t = (c_0, c_1, c_2, c_3)$ will usually be written in the form

$$\boxed{\begin{array}{ccc} & c_0 & \\ c_3 & & c_1 \\ & c_2 & \end{array}}\,.$$

And we will often refer to its single colors as t_{top}, t_{right}, t_{bottom} and t_{left}.

Let C be a set of colors, $T \subseteq C^4$ a finite set of tiles and $\mathfrak{A} = (A, V, H)$ a first-order structure with binary relations V and H interpreted as vertical and horizontal successor relations. Then a *T-tiling* of $\mathfrak{A}$ is a total function $t \colon A \to T$ such that for all $x, y \in A$ it holds that

a) $t(x)_{\text{top}} = t(y)_{\text{bottom}}$ if $(x, y) \in V$, i. e. the top color of x matches the bottom color of y, and

b) $t(x)_{\text{right}} = t(y)_{\text{left}}$ if $(x, y) \in H$, i. e. the right color of x matches the left color of y.

A *periodic* T-tiling of $\mathfrak{A}$ (with period $m \times n$) is a T-tiling t of $\mathfrak{A}$ such that there are $m, n \geqslant 1$ with

$$t(x)_{\text{left}} = t(y)_{\text{left}} \text{ for all } x, y \in A \text{ with } (x, y) \in H^m$$

and

$$t(x)_{\text{bottom}} = t(y)_{\text{bottom}} \text{ for all } x, y \in A \text{ with } (x, y) \in V^n,$$

i. e. there is a rectangle of tiles of size $m \times n$ which can be concatenated arbitrarily often in both directions (if V and H are total relations in $\mathfrak{A}$).

Now additionally let $c \in C$ be a color. Then a *(bordered)* (T, c)*-tiling* of $\mathfrak{A}$ is a T-tiling t of $\mathfrak{A}$ such that for all $x \in A$ it holds that

$$\begin{array}{lll} t(x)_{\text{left}} = c & \text{if} & \text{there is no } y \in A \text{ with } (y, x) \in H, \\ t(x)_{\text{bottom}} = c & \text{if} & \text{there is no } y \in A \text{ with } (y, x) \in V, \\ t(x)_{\text{right}} = c & \text{if} & \text{there is no } y \in A \text{ with } (x, y) \in H \text{ and} \\ t(x)_{\text{top}} = c & \text{if} & \text{there is no } y \in A \text{ with } (x, y) \in V, \end{array}$$

i. e. the borders of $\mathfrak{A}$ (so far as they exist) are all c-colored. ⌟

Next we define tiling problems for classes of structures.

Definition 6.8. A structure $\mathfrak{A} = (A, V, H)$ is called (periodically) T*-tilable* (resp. (T, c)-tilable) iff there is a (periodic) T-tiling (resp. bordered (T, c)-tiling) of $\mathfrak{A}$.

For any class $\mathcal{C}$ of structures over the vocabulary $\{V, H\}$ we define the problems

$$\textsc{Tiling}(\mathcal{C}) := \{T \mid \text{there is an } \mathfrak{A} \in \mathcal{C} \text{ such that } \mathfrak{A} \text{ is } T\text{-tilable}\},$$

$$\textsc{PeriodicTiling}(\mathcal{C}) := \{T \mid \text{there is an } \mathfrak{A} \in \mathcal{C} \text{ such that } \mathfrak{A} \text{ is periodically } T\text{-tilable}\}$$

and

$$\textsc{BorderedTiling}(\mathcal{C}) := \{(T, c) \mid \text{there is an } \mathfrak{A} \in \mathcal{C} \text{ such that } \mathfrak{A} \text{ is } (T, c)\text{-tilable}\}.$$

We usually write $\textsc{Tiling}(\mathfrak{A})$ instead of $\textsc{Tiling}(\{\mathfrak{A}\})$ – and analogous for the other two problems. ⌟

Later we will use the following theorems to show the undecidability of $\mathcal{IF}^2$-SAT and $\mathcal{IF}^2$-FINSAT.

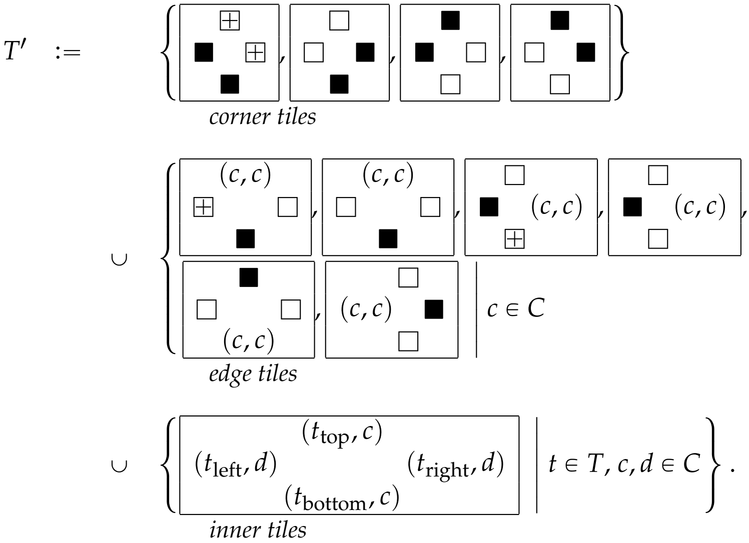
Theorem 6.9 ([Ber66], [Har86]). TILING($\mathfrak{G}$) *is* Π^0_1*-complete.*

Theorem 6.10 ([GK72]). PERIODICTILING($\mathfrak{G}$) *is* Σ^0_1*-complete.*

Theorem 6.11. BORDEREDTILING(FinGrid) *is* Σ^0_1*-complete.*[1]

PROOF OF THEOREM 6.11. For the upper bound note that all possible solutions are finite and can be recursively enumerated and checked.

For the lower bound we give a reduction from PERIODICTILING($\mathfrak{G}$). For this purpose let C be a set of colors and let T be an arbitrary set of tiles over C. Then we define a new set of colors $C' := (C \times C) \cup \{\blacksquare, \square, \boxplus\}$ where $\blacksquare$, $\square$ and $\boxplus$ are new colors not included in C. And we define a new set of tiles

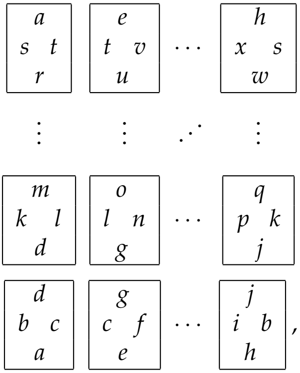


We will now prove that there is a periodic T-tiling of the infinite grid iff there is a bordered $(T', \blacksquare)$-tiling of a finite grid. Thus, the construction of T' from T is a reduction from PERIODICTILING($\mathfrak{G}$) to BORDEREDTILING(FinGrid) and therefore, by Theorem 6.10, BORDEREDTILING(FinGrid) is Σ^0_1-hard.

---

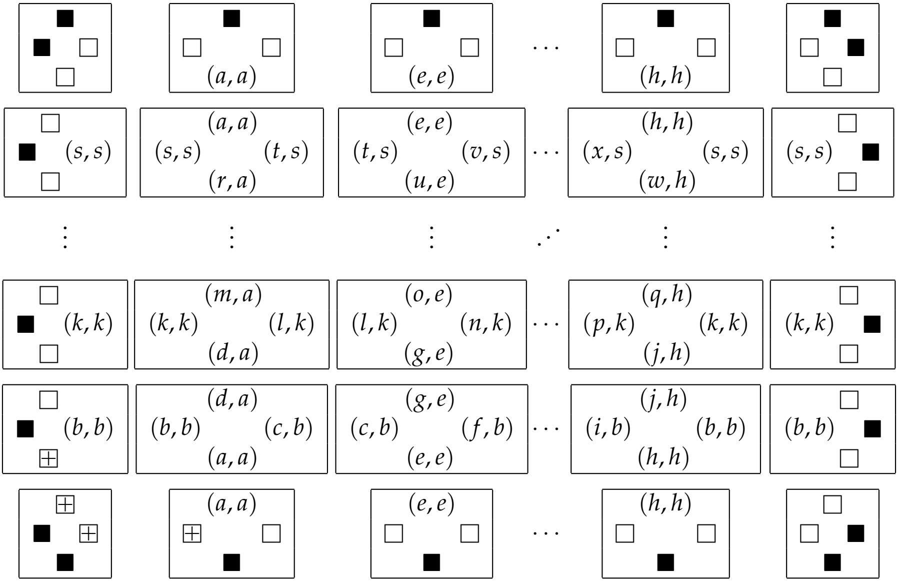
[1] In [vEB96] a very similar problem is proven to be Σ^0_1-hard. Their technique, however, is completely different from ours.

Now, first let there be a periodic T-tiling of $\mathfrak{G}$ with period $m \times n$ which is composed of repetitions of the rectangle

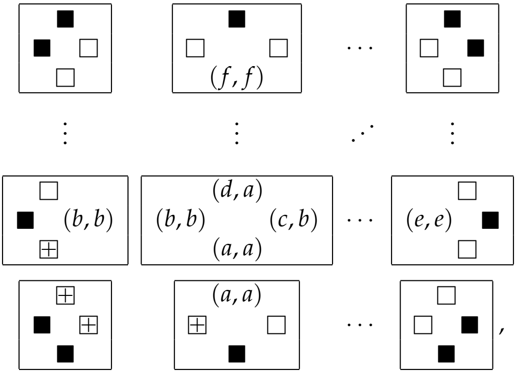


with $a, b, c, \ldots \in C$.

Then the following is a bordered $(T', \blacksquare)$-tiling of $\mathfrak{G}_{(m+2)\times(n+2)}$:



For the reverse direction let there be a bordered $(T', \blacksquare)$-tiling of $\mathfrak{G}_{m\times n}$. Because the corner and edge tiles of T' are the only tiles with the color $\blacksquare$ the tiling is of the form



,

with $a, b, c \in C$. Since the bottom left corner tile uses the color $\boxplus$ instead of $\square$ we know that $m, n \geqslant 3$, i. e. there is at least one inner tile in the tiling. And due to the definition of the first components of the colors of the inner tiles of T' it follows that the first components in the inner tiles in the above tiling form a partial T-tiling of $\mathfrak{G}$ with size $(m-2) \times (n-2)$. Now, because of the definition of the second components in the inner tiles of T' it follows that $a = f$, $b = e$ etc., i. e. the partial T-tiling is the defining rectangle of a periodic T-tiling of $\mathfrak{G}$ which therefore exists. ∎

To prove the undecidability of $\mathcal{IF}^2$-SAT (Theorem 6.19) and $\mathcal{IF}^2$-FINSAT (Theorem 6.23) we will, for every set of tiles T, define a formula ϕ_T such that $\mathfrak{A}$ has a T-tiling iff there is an expansion $\mathfrak{A}^*$ of $\mathfrak{A}$ with $\mathfrak{A}^* \models \phi_T$. Then we will define another formula ϕ_{grid} and show that $\mathfrak{A} \models \phi_{\text{grid}}$ iff $\mathfrak{A}$ contains a substructure isomorphic to a grid. Therefore $\phi_T \wedge \phi_{\text{grid}}$ is satisfiable if and only if there is a T-tiling of a grid. For $\mathcal{IF}^2$-SAT we will additionally ensure that this grid is the infinite grid and for $\mathcal{IF}^2$-FINSAT (Section 6.2.1) we will extend ϕ_T by a formula $\phi_{c,T}$ ensuring that $\mathfrak{A}^*$ has a bordered (T, c)-tiling.

Definition 6.12. Let $T = \{t^0, \ldots, t^k\}$ be a set of tiles and for all $i \leqslant k$ let $\text{right}(t^i)$ (resp. $\text{top}(t^i)$) be the set

$$\{t^j \in \{t^0, \ldots, t^k\} \mid t^i_{\text{right}} = t^j_{\text{left}} \text{ (resp. } t^i_{\text{top}} = t^j_{\text{bottom}})\},$$

i. e. the set of tiles matching t^i to the right (resp. top).

Then we define the first-order formulas

$$\begin{aligned}
\psi_T &:= \forall x \forall y \Big(\big(H(x,y) \to \bigwedge_{i \leqslant k} \big(P_i(x) \to \bigvee_{t^j \in \mathrm{right}(t^i)} P_j(y)\big)\big) \wedge \\
&\qquad\qquad \big(V(x,y) \to \bigwedge_{i \leqslant k} \big(P_i(x) \to \bigvee_{t^j \in \mathrm{top}(t^i)} P_j(y)\big)\big)\Big), \\
\theta_T &:= \forall x \bigvee_{i \leqslant k} \big(P_i(x) \wedge \bigwedge_{\substack{j \leqslant k \\ j \neq i}} \neg P_j(x)\big) \text{ and} \\
\phi_T &:= \psi_T \wedge \theta_T
\end{aligned}$$

over the vocabulary $V, H, P_0, \ldots, P_k$. Here, $\phi \to \psi$ is an abbreviation of $\phi^{\mathrm{d}} \vee \psi$. ⌟

Note that our semantics for the implication operator leads to the same semantics as the usual first-order definition of $\phi \to \psi$ being an abbreviation for $\neg\phi \vee \psi$ because in the first-order case ϕ^{d} is nothing else than the negation normal form of $\neg\phi$ (cf. Definition 2.9). However, our definition uses negation only directly in front of atomic formulas and is thus compatible with our definitions of formulas to always be in negation normal form (cf. Sections 2.1 and 3.1).

With the previously defined formulas we can now express the T-tilability of a given structure.

Lemma 6.13. *Let $T = \{t_0, \ldots, t_k\}$ be a set of tiles and $\mathfrak{A} = (A, V, H)$ a structure. Then $\mathfrak{A}$ is T-tilable iff there is an expansion $\mathfrak{A}^* = (A, V, H, P_0, \ldots, P_k)$ of $\mathfrak{A}$ such that $\mathfrak{A}^* \models \phi_T$.*

Notice that ϕ_T is an $\mathcal{FO}^2$-sentence. Therefore T-tiling is expressible even in $\mathcal{FO}^2$. The difficulty lies in expressing that a structure is (or at least contains) a grid. This is the part of the construction where $\mathcal{FO}^2$ or even $\mathcal{D}^2$ formulas are no longer sufficient and the full expressivity of $\mathcal{IF}^2$ is needed.

Definition 6.14. A structure $\mathfrak{A} = (A, V, H)$ is called *grid-like* iff it satisfies the conjunction ϕ_{grid} of the formulas

$$\begin{aligned}
\phi_{\text{SWroot}} &:= \exists x \Big(\forall y \big(\neg V(y,x) \wedge \neg H(y,x) \big) \Big), \\
\phi_{\text{functional}} &:= \forall x \forall y \big(R(x,y) \rightarrow \exists x/\{y\}\, y = x \big) \\
&\qquad \text{for } R \in \{V, H\}, \\
\phi_{\text{injective}} &:= \forall x \forall y \big(R(x,y) \rightarrow \exists y/\{x\}\, x = y \big) \\
&\qquad \text{for } R \in \{V, H\}, \\
\phi_{\text{distinct}} &:= \forall x \forall y\, \neg \big(V(x,y) \wedge H(x,y) \big), \\
\phi_{\text{SWedges}} &:= \forall x \Big(\big(\forall y\, \neg R(y,x) \big) \rightarrow \forall y \big((R'(x,y) \vee R'(y,x)) \rightarrow \forall x\, \neg R(x,y) \big) \Big) \\
&\qquad \text{for } (R, R') \in \{(V,H), (H,V)\}, \\
\phi_{\text{NEedges}} &:= \forall x \Big(\big(\forall y\, \neg R(x,y) \big) \rightarrow \forall y \big((R'(x,y) \vee R'(y,x)) \rightarrow \forall x\, \neg R(y,x) \big) \Big) \\
&\qquad \text{for } (R, R') \in \{(V,H), (H,V)\}, \\
\phi_{\text{join}} &:= \forall x \Big(\big(\exists y V(x,y) \wedge \exists y H(x,y) \big) \rightarrow \forall y \Big(\big(V(x,y) \vee H(x,y) \big) \\
&\qquad \rightarrow \exists x/\{y\}\, \big(V(y,x) \vee H(y,x) \big) \Big) \Big).
\end{aligned}$$

⌟

The grid-likeness of a structure can alternatively be described in the following more intuitive way.

Remark 6.15. *A structure $\mathfrak{A} = (A, V, H)$ is grid-like iff*

a) *V and H are (graphs of) injective partial functions, i. e. the in- and out-degree of every element is at most one ($\phi_{\text{functional}}$ and $\phi_{\text{injective}}$),*

b) *there exists a point SW that does not have any predecessors (ϕ_{SWroot}),*

c) *for every element its V-successor is distinct from its H-successor (ϕ_{distinct}),*

d) *for every element x such that x does not have a V- (resp. H-) predecessor, the H- (resp. V-) successor and -predecessor of x also do not have a V- (resp. H-) predecessor (ϕ_{SWedges}),*

e) *for every element x such that x does not have a V- (resp. H-) successor, the H- (resp. V-) successor and -predecessor of x also do not have a V- (resp. H-) successor (ϕ_{NEedges}),*

f) *for every element x that has a V-successor and an H-successor there is an element y such that $(x,y) \in (V \circ H) \cap (H \circ V)$ or $(x,y) \in (V \circ V) \cap (H \circ H)$.*

PROOF. The only difficulty is the connection between property f) and formula ϕ_{join}. First note that ϕ_{join} is equivalent to the first-order formula

$$\begin{aligned}\forall x\Big(&\big(\exists z V(x,z) \wedge \exists z H(x,z)\big) \rightarrow \\ &\qquad \exists x' \forall y\Big(\big(V(x,y) \vee H(x,y)\big) \rightarrow \big(V(y,x') \vee H(y,x')\big)\Big)\Big).\end{aligned}$$

Since $\phi_{\text{functional}}$ and ϕ_{distinct} hold as well, this implies

$$\begin{aligned}\forall x\Big(&\big(\exists z V(x,z) \wedge \exists z H(x,z)\big) \rightarrow \exists x' \exists y_1 \exists y_2\Big(y_1 \neq y_2 \wedge V(x,y_1) \wedge H(x,y_2) \\ &\qquad \wedge \big(V(y_1,x') \vee H(y_1,x')\big) \wedge \big(V(y_2,x') \vee H(y_2,x')\big)\Big)\Big).\end{aligned}$$

Due to $\phi_{\text{injective}}$ neither $V(y_1,x') \wedge V(y_2,x')$ nor $H(y_1,x') \wedge H(y_2,x')$ can be true if $y_1 \neq y_2$. Hence, from the above it follows that

$$\begin{aligned}\forall x\Big(&\big(\exists z V(x,z) \wedge \exists z H(x,z)\big) \rightarrow \exists x' \exists y_1 \exists y_2\Big(y_1 \neq y_2 \\ &\wedge \Big(\big(V(x,y_1) \wedge H(x,y_2) \wedge V(y_1,x') \wedge H(y_2,x')\big) \\ &\qquad \vee \big(V(x,y_1) \wedge H(x,y_2) \wedge H(y_1,x') \wedge V(y_2,x')\big)\Big)\Big)\Big).\end{aligned}$$

From this formula the property f) is immediate (with $x := x$ and $y := x'$). The reverse direction can be shown similarly but it will not be needed anyway. ■

Now we will use Remark 6.15 to show that a grid-like structure, although it does not need to be a grid itself, must at least contain a component that is isomorphic to a grid. Here, by *component* we mean a maximal weakly connected substructure, i. e. $\mathfrak{B}$ is a component of $\mathfrak{A} = (A, V, H)$ iff $\mathfrak{B}$ is an induced substructure of $\mathfrak{A}$ such that between any two elements from B there is a path along $R := V \cup H \cup V^{-1} \cup H^{-1}$ and B is closed under following edges from R.

Theorem 6.16. *Let $\mathfrak{A} = (A, V, H)$ be a grid-like structure. Then $\mathfrak{A}$ contains a component that is isomorphic to a grid.*

PROOF. Due to ϕ_{SWroot} there exists a point $SW \in A$ that has a V- and an H-successor but no V- or H-predecessor. Now let n be the smallest natural number such that for all $x \in A$ it holds that $(SW, x) \notin V^{n+1}$. If such a number does not exist let $n := \infty$. Since, by Remark 6.15a, V is an injective partial function and SW does not have a V-predecessor the latter case can only occur if A is infinite. Analogously define $m \in \mathbb{N} \cup \{\infty\}$ as the smallest number such that for all $x \in A$ it holds that $(SW, x) \notin H^{n+1}$ or as ∞.

We will show that $\mathfrak{A}$ has a component that is isomorphic to $\mathfrak{G}_{m \times n}$. For this purpose we first prove by induction on $1 \leqslant k \leqslant n$ that $\mathfrak{A}$ has an in-degree complete substructure isomorphic to $\mathfrak{G}_{m \times n}$ – with $(0,0)$ mapped to SW. Here, we call a substructure $\mathfrak{H}$ of $\mathfrak{A}$ *in-degree complete* if every point in $\mathfrak{H}$ has the same in-degrees in $\mathfrak{H}$ as it has in $\mathfrak{A}$.

By selection of m the point SW has an H^i-successor u_i for each $0 \leqslant i \leqslant m$ (whenever we write $i \leqslant m$ we naturally mean that the case $i = m$ is only included if $m < \infty$). Since H is an injective partial function and SW has no H-predecessor the points u_i are all distinct and unique. Due to ϕ_{SWedges} none of the points u_i has a V-predecessor and therefore the V-successors of the points u_i are not in the set $\{u_i \mid i \leqslant m\}$. Therefore $\mathfrak{A} \upharpoonright \{u_i \mid i \leqslant m\}$ is isomorphic to $\mathfrak{G}_{m \times 1}$. Due to ϕ_{SWedges}, ϕ_{SWroot} and $\phi_{\text{injective}}$ the structure $\mathfrak{A} \upharpoonright \{u_i \mid i \leqslant m\}$ is in-degree complete.

For the induction step assume that there is an in-degree complete substructure $\mathfrak{B}$ of $\mathfrak{A}$ which is isomorphic to $\mathfrak{G}_{m \times k}$ for a $k < n$ such that $(0,0)$ is mapped to SW. Let h be the isomorphism from $\mathfrak{G}_{m \times k}$ to $\mathfrak{B}$. We will now extend h to h' such that h' is an isomorphism from $\mathfrak{G}_{m \times (k+1)}$ to a substructure of $\mathfrak{A}$. Since $k + 1 \leqslant n$ there exists a point $a_0 \in A$ such that a_0 is the V-successor of $h((0,k))$. Due to ϕ_{NEedges} and since $h((0,k))$ has a V-successor, each of the points $h((i,k))$, $i \leqslant m$, has a V-successor a_i. Since V is a partial injective function and the points $h((i,k))$ are all distinct, the points a_i are also all distinct. And since the structure $\mathfrak{B}$ is in-degree complete, none of the points a_i nor any of their $(V \cup H)$-successors is in B.

Next, we will show that a_{i+1} is the H-successor of a_i for all $i < m$. For $i \leqslant m - 2$, the point $h((i,k))$ has an H^2- but no V^2-successor in $\mathfrak{B}$. Hence, for all $i \leqslant m - 2$, if the V^2-successor of $h((i,k))$ exists in $\mathfrak{A}$, it cannot be the same as the H^2-successor of $h((i,k))$. Also notice that each of the points $h((i,k))$, $i \leqslant m - 2$, has a V- and an H-successor in $\mathfrak{A}$. Therefore due to Remark 6.15f the $(V \circ H)$-successor and the $(H \circ V)$-successor of the point $h((i,k))$, $i \leqslant m - 2$, are the same. Therefore the H-successor of a_i is a_{i+1} for all $i \leqslant m - 2$.

In the case $m < \infty$ it still needs to be shown that a_m is the H-successor of a_{m-1}. For this purpose note that the point $h((m-1,k))$ has no H^2-successor in $\mathfrak{A}$ since $h((m,k))$ does not have an H-successor (due to ϕ_{NEedges} and the selection of m). Hence, there cannot be a point a in $\mathfrak{A}$ such that it is both an H^2- and a V^2-successor of $h((m-1,k))$. Now due to Remark 6.15f and the fact that $h((m-1,k))$ has a V- and an H-successor in $\mathfrak{A}$, the $(H \circ V)$- and the

$(V \circ H)$-successor of $h((m-1,k))$ have to be the same. Therefore a_m is the H-successor of a_{m-1}.

We define $h' := h \cup \{(i,k+1) \mapsto a_i \mid i \leqslant m\}$. Each point a_i (with the exception of a_0 which has no H-predecessor at all due to ϕ_{SWedges}) has a_{i-1} as H-predecessor. Hence, due to the in-degree completeness of $\mathfrak{B}$, injectivity of V and H and since each of the points a_i has a V-predecessor in B, we conclude that the structure $\mathfrak{A} \upharpoonright \text{range}(h')$ is an in-degree complete substructure of $\mathfrak{A}$. We also notice that due to injectivity, the points a_i have no reflexive loops. Due to the in-degree completeness of $\mathfrak{B}$ none of the $(V \cup H)$-successors of the points a_i, $i \leqslant m$, are in B. Hence it is straightforward to observe that h' is the desired isomorphism from $\mathfrak{G}_{m\times(k+1)}$ to an in-degree complete substructure of $\mathfrak{A}$.

We have now proven that $\mathfrak{A}$ has an in-degree complete substructure $\mathfrak{B}$ such that there is an isomorphism h from $\mathfrak{G}_{m\times n}$ to $\mathfrak{B}$ with $h((0,0)) = SW$. If $n < \infty$ then, by definition of n, the point $h((0,n))$ has no V-successor. Therefore due to ϕ_{NEedges} none of the points $h((i,n))$, $i \leqslant m$, has a V-successor in $\mathfrak{A}$. If on the other hand $n = \infty$ then, again by definition of n and ϕ_{NEedges}, each of the infinite many points $h((i,j))$, $i \leqslant m$, $j \in \mathbb{N}$, has a V-successor in $\mathfrak{B}$. These facts together with functionality and injectivity of V and the in-degree completenes of $\mathfrak{B}$ implies that in both cases $\mathfrak{B}$ is closed under V and V^{-1}, i. e.

$$B \cup \{b \mid \text{there is } a \in B \text{ with } (a,b) \in V \text{ or } (b,a) \in V\} = A.$$

Analogously it can be shown that $\mathfrak{B}$ is also closed under H and H^{-1}. Hence, $\mathfrak{B}$ is in fact a component of $\mathfrak{A}$. ■

Now we will use the previous result to define a formula that ensures containment of the infinite grid.

Corollary 6.17. *Let $\mathfrak{A} = (A, V, H)$ be a structure that satisfies the conjunction ϕ_{infgrid} of ϕ_{grid} and the formulas*

$$\phi_{\text{infinite}}(R) := \forall x \exists y R(x,y) \quad \textit{for } R \in \{V, H\}.$$

Then $\mathfrak{A}$ contains a component that is isomorphic to the infinite grid $\mathfrak{G}$.

Proof. By Theorem 6.16 we know that $\mathfrak{A}$ contains a component $\mathfrak{B}$ that is isomorphic to $\mathfrak{G}_{m\times n}$ for some $m, n \in \mathbb{N} \cup \{\infty\}$. Now suppose that $m < \infty$ and let h be the isomorphism from $\mathfrak{G}_{m\times n}$ to $\mathfrak{B}$. Then $h((m,0))$ cannot have an H-successor in $\mathfrak{A}$ since $\mathfrak{B}$ is a component in $\mathfrak{A}$ (and as such is closed under H), $\mathfrak{B}$ is isomorphic to $\mathfrak{G}_{m\times n}$ and $(m,0)$ does not have an H-successor in $\mathfrak{G}_{m\times n}$. But this is a contradiction to $\phi_{\text{infinite}}(H)$ and therefore $m = \infty$. For analogous reasons it follows that $n = \infty$ and, hence, $\mathfrak{B}$ is isomorphic to $\mathfrak{G}$. ■

The last tool needed to prove the main theorem is the following lemma about tilability of components.

Lemma 6.18. *Let C be a set of colors, T a set of tiles over C, $c \in C$ a color and $\mathfrak{B} = (B, V, H)$ a structure. Then $\mathfrak{B}$ is T-tilable (resp. (T, c)-tilable) iff there is a structure $\mathfrak{A}$ which is T-tilable (resp. (T, c)-tilable) and contains a component that is isomorphic to $\mathfrak{B}$.*

PROOF. The direction from left to right is trivial since every structure has itself as a component. For the reverse direction the T-tilability of $\mathfrak{B}$ is also obvious since the matching of neighboring colors is clearly preserved under taking arbitrary substructures.

For the property of (T, c)-tilability on the other hand it is necessary that $\mathfrak{B}$ is in fact isomorphic to a *component* and not only to any substructure of $\mathfrak{A}$: If t is a (T, c)-tiling of $\mathfrak{A}$ and $\mathfrak{B}$ is isomorphic to a component of $\mathfrak{A}$ then assume there is a $x \in B$ such that, for example, x does not have a H-predecessor in $\mathfrak{B}$ but also $t(x)_{\text{left}} \neq c$. From this follows that x does not have a H-predecessor in $\mathfrak{A}$ since $\mathfrak{B}$ is isomorphic to a component of $\mathfrak{A}$, i. e. a *maximal* weakly connected substructure. But this is a contradiction to t being a (T, c)-tiling of $\mathfrak{A}$. ∎

The following is the main theorem of this section.

Theorem 6.19. *$\mathcal{IF}^2$-SAT is Π^0_1-complete.*

PROOF. For the upper bound note that $\mathcal{FO}$-SAT $\in \Pi^0_1$ by Gödel's completeness theorem. By Remark 2.19 it follows that $\mathcal{ESO}$-SAT $\in \Pi^0_1$ and by the computable translation from $\mathcal{D}$ to $\mathcal{ESO}$ from [Vää07, Theorem 6.2] it follows that $\mathcal{D}^3$-SAT $\in \Pi^0_1$. Finally, the computability of the reductions in Lemma 6.2 and Theorem 6.3 implies that $\mathcal{IF}^2$-SAT $\in \Pi^0_1$.

The lower bound follows by Theorem 6.9 and the reduction g from TILING($\mathfrak{G}$) to $\mathcal{IF}^2$-SAT defined by $g(T) := \phi_{\text{infgrid}} \wedge \phi_T$. To see that g indeed is such a reduction, first let T be a set of tiles such that $\mathfrak{G}$ is T-tilable. Then, by Lemma 6.13, it follows that there is an expansion $\mathfrak{G}^*$ of $\mathfrak{G}$ such that $\mathfrak{G}^* \models \phi_T$. Clearly, $\mathfrak{G}^* \models \phi_{\text{infgrid}}$ and therefore $\mathfrak{G}^* \models \phi_{\text{infgrid}} \wedge \phi_T$.

If, on the other hand, $\mathfrak{A}^*$ is a structure such that $\mathfrak{A}^* \models \phi_{\text{infgrid}} \wedge \phi_T$, then, by Corollary 6.17, the $\{V, H\}$-reduct $\mathfrak{A}$ of $\mathfrak{A}^*$ contains a component that is isomorphic to $\mathfrak{G}$. Furthermore, by Lemma 6.13, $\mathfrak{A}$ is T-tilable. Hence, by Lemma 6.18, $\mathfrak{G}$ is T-tilable. ∎

6.2.1 FINITE SATISFIABILITY IS UNDECIDABLE FOR $\mathcal{IF}^2$

We will now discuss the problem $\mathcal{IF}^2$-FINSAT whose undecidability proof is similar to the above. The main difference is that we will now use bordered instead of arbitrary tilings.

Therefore we first need to be able to express the containment of a finite grid.

Corollary 6.20. *Let $\mathfrak{A} = (A, V, H)$ be a finite grid-like structure. Then $\mathfrak{A}$ contains a component that is isomorphic to a grid $\mathfrak{G}_{m\times n}$ for some $m, n \in \mathbb{N}$.*

PROOF. By Theorem 6.16 there is a component $\mathfrak{B}$ of $\mathfrak{A}$ that is isomorphic to a grid $\mathfrak{G}_{m\times n}$ for some $m, n \in \mathbb{N} \cup \{\infty\}$. Thus we only have to show that $m, n < \infty$. Now suppose that $m = \infty$ and let h be the isomorphism from $\mathfrak{G}_{\infty\times n}$ to $\mathfrak{B}$. Then $h((0,0)), h((1,0)), h((2,0)), \ldots$ is an infinite sequence of pairwise-distinct points since $h((0,0))$ does not have an H-predecessor and H is injective. But this is a contradiction to the finiteness of $\mathfrak{A}$. For analogous reasons it holds that $m < \infty$. ■

Next we define some formulas dealing with border colors.

Definition 6.21. Let C be a set of colors, $T = \{t^0, \ldots, t^k\}$ a set of tiles over C and $c \in C$ a color. Furthermore let

$$T_{c,dir} := \{t^i \mid t^i_{dir} = c\},$$

for $dir \in \{\text{top}, \text{right}, \text{bottom}, \text{left}\}$, i. e. the set of tiles with c-colored dir edge.

Then $\phi_{c,T}$ is defined as the conjunction of the $\mathcal{FO}^2$ formulas

$$\begin{aligned}
\phi_{c,T,\text{bottom}} &:= \forall x\Big((\forall y \neg V(y,x)) \rightarrow \bigvee_{t^i \in T_{c,\text{bottom}}} P_i(x)\Big),\\
\phi_{c,T,\text{left}} &:= \forall x\Big((\forall y \neg H(y,x)) \rightarrow \bigvee_{t^i \in T_{c,\text{left}}} P_i(x)\Big),\\
\phi_{c,T,\text{top}} &:= \forall x\Big((\forall y \neg V(x,y)) \rightarrow \bigvee_{t^i \in T_{c,\text{top}}} P_i(x)\Big) \text{ and}\\
\phi_{c,T,\text{right}} &:= \forall x\Big((\forall y \neg H(x,y)) \rightarrow \bigvee_{t^i \in T_{c,\text{right}}} P_i(x)\Big).
\end{aligned}$$

⌟

The following obvious extension of Lemma 6.13 now shows how to express (T, c)-tilability.

Lemma 6.22. *Let C be a set of colors, $T = \{t_0, \dots, t_k\}$ a set of tiles over C, $c \in C$ and $\mathfrak{A} = (A, V, H)$ a structure. Then $\mathfrak{A}$ is (T, c)-tilable iff there is an expansion $\mathfrak{A}^* = (A, V, H, P_0, \dots, P_k)$ of $\mathfrak{A}$ such that $\mathfrak{A}^* \models \phi_T \wedge \phi_{c,T}$.*

Finally, the following theorem is the finite analogon of Theorem 6.19.

Theorem 6.23. *$\mathcal{IF}^2$-FINSAT is Σ^0_1-complete.*

PROOF. For the upper bound note that since all finite structures can be recursively enumerated and the model checking problem of $\mathcal{IF}^2$ over finite models is clearly decidable we have $\mathcal{IF}^2$-FINSAT $\in \Sigma^0_1$.

The lower bound now follows by Theorem 6.11 and the reduction g from BORDEREDTILING(FinGrid) to our problem defined by

$$g((T, c)) := \phi_{\text{grid}} \wedge \phi_T \wedge \phi_{c,T}.$$

To see that g indeed is such a reduction, first let C be a set of colors, T a set of tiles over C, $c \in C$ a color and $m, n \in \mathbb{N}$ such that there is a bordered (T, c)-tiling of $\mathfrak{G}_{m\times n}$. Then, by Lemma 6.22, it follows that there is an expansion $\mathfrak{G}^*_{m\times n}$ of $\mathfrak{G}_{m\times n}$ such that $\mathfrak{G}^*_{m\times n} \models \phi_T \wedge \phi_{c,T}$. Clearly, $\mathfrak{G}^*_{m\times n} \models \phi_{\text{grid}}$ and therefore $\mathfrak{G}^*_{m\times n} \models \phi_{\text{grid}} \wedge \phi_T \wedge \phi_{c,T}$.

If, on the other hand, $\mathfrak{A}^*$ is a finite structure such that $\mathfrak{A}^* \models \phi_{\text{grid}} \wedge \phi_T \wedge \phi_{c,T}$ then, by Corollary 6.20, the $\{V, H\}$-reduct $\mathfrak{A}$ of $\mathfrak{A}^*$ contains a component that is isomorphic to $\mathfrak{G}_{m\times n}$ for some $m, n \in \mathbb{N}$. Furthermore, by Lemma 6.22, $\mathfrak{A}$ is (T, c)-tilable. Hence, by Lemma 6.18, $\mathfrak{G}_{m\times n}$ is (T, c)-tilable. ■

6.3 SATISFIABILITY IS NEXPTIME-COMPLETE FOR $\mathcal{D}^2$

In this section we show that $\mathcal{D}^2$-SAT and $\mathcal{D}^2$-FINSAT are NEXP-complete. Our proof uses the fact that $\mathcal{FOC}^2$-SAT and $\mathcal{FOC}^2$-FINSAT are NEXP-complete [PH05].

Theorem 6.24. *Let τ be a relational vocabulary. For every formula $\phi \in \mathcal{D}^2[\tau]$ there is a sentence $\phi^* \in \mathcal{ESO}[\tau \cup \{R\}]$ (with $\text{arity}(R) = |\text{Fr}(\phi)|$),*

$$\phi^* := \exists R_1 \dots \exists R_k \psi,$$

where R_i is of arity at most 2 and $\psi \in \mathcal{FOC}^2$, such that for all $\mathfrak{A}$ and teams X with $\text{dom}(X) = \text{Fr}(\phi)$ it holds that

$$\mathfrak{A} \models_X \phi \quad \textit{iff} \quad (\mathfrak{A}, \text{rel}(X)) \models \phi^*, \tag{6.13}$$

where $(\mathfrak{A}, \mathrm{rel}(X))$ *is the expansion* $\mathfrak{A}'$ *of* $\mathfrak{A}$ *into vocabulary* $\tau \cup \{R\}$ *defined by* $R^{\mathfrak{A}'} := \mathrm{rel}(X)$.

PROOF. Using induction on ϕ we will first translate ϕ into a sentence $\widetilde{\phi} \in \mathcal{ESO}[\tau \cup \{R\}]$ satisfying Eq. (6.13). Then we note that $\widetilde{\phi}$ can be translated into an equivalent sentence ϕ^* that also satisfies the syntactic requirement of the theorem. The proof is a modification of the proof from [Vää07, Theorem 6.2]. Below we write $\phi(x,y)$ to indicate that $\mathrm{Fr}(\phi) = \{x,y\}$. Also, the quantified relations S and T below are assumed not to appear in $\widetilde{\psi}$ and $\widetilde{\theta}$.

a) Let $\phi(x,y) \in \{x = y, \neg x = y, P(x,y), \neg P(x,y)\}$. Then $\widetilde{\phi}$ is defined as

$$\forall x \forall y (R(x,y) \to \phi(x,y)).$$

b) Let $\phi(x,y)$ be of the form $=\!(x,y)$. Then $\widetilde{\phi}$ is defined as

$$\forall x \exists^{\leqslant 1} y R(x,y).$$

c) Let $\phi(x,y)$ be of the form $\neg{=}(x,y)$. Then $\widetilde{\phi}$ is defined as

$$\forall x \forall y \neg R(x,y).$$

d) Let $\phi(x,y)$ be of the form $\psi(x,y) \vee \theta(y)$. Then $\widetilde{\phi}$ is defined as

$$\exists S \exists T (\widetilde{\psi}(S/R) \wedge \widetilde{\theta}(T/R) \wedge \forall x \forall y (R(x,y) \to (S(x,y) \vee T(y)))).$$

e) Let $\phi(x)$ be of the form $\psi(x) \vee \theta$. Then $\widetilde{\phi}$ is defined as

$$\exists S \exists T (\widetilde{\psi}(S/R) \wedge \widetilde{\theta}(T/R) \wedge \forall x (R(x) \to (S(x) \vee T))).$$

f) Let $\phi(x,y)$ be of the form $\psi(x) \wedge \theta(y)$. Then $\widetilde{\phi}$ is defined as

$$\exists S \exists T (\widetilde{\psi}(S/R) \wedge \widetilde{\theta}(T/R) \wedge \forall x \forall y (R(x,y) \to (S(x) \wedge T(y)))).$$

g) Let $\phi(x)$ be of the form $\exists y \psi(x,y)$. Then $\widetilde{\phi}$ is defined as

$$\exists S (\widetilde{\psi}(S/R) \wedge \forall x \exists y (R(x) \to S(x,y))).$$

h) Let $\phi(x)$ be of the form $\forall y \psi(x,y)$. Then $\widetilde{\phi}$ is defined as

$$\exists S (\widetilde{\psi}(S/R) \wedge \forall x \forall y (R(x) \to S(x,y))).$$

Note that we have not displayed all the possible cases, e. g. ϕ of the form $=\!(x)$ or $P(x)$, for which $\widetilde{\phi}$ is defined analogously to the above. Note also that, for convenience, we allow 0-ary relations in the translation. The possible interpretations of a 0-ary relation R are $\emptyset$ and $\{\emptyset\}$. For a 0-ary R we define $\mathfrak{A} \models R$ if and only if $R^{\mathfrak{A}} = \{\emptyset\}$. Clause e) exemplifies the use of 0-ary relations in the translation. It is easy to see that $\widetilde{\phi}$ in e) is equivalent to

$$\exists S(\widetilde{\theta}(\top/R) \vee (\widetilde{\psi}(S/R) \wedge \forall x(R(x) \to S(x)))).$$

Generally, the use of 0-ary relations in the translation can be easily eliminated with no essential change.

A straightforward induction on ϕ shows that $\widetilde{\phi}$ can be transformed into ϕ^* of the form

$$\exists R_1 \ldots \exists R_k(\forall x \forall y \psi \wedge \bigwedge_i \forall x \exists y \theta_i \wedge \bigwedge_j \forall x \exists^{\leqslant 1} y R_{m_j}(x,y)),$$

where ψ and θ_i are quantifier-free. ■

Note that if $\phi \in \mathcal{D}^2$ is a sentence then the relation symbol R is 0-ary and $\mathrm{rel}(X)$ (and $R^{\mathfrak{A}}$) is either $\emptyset$ or $\{\emptyset\}$. Hence, Theorem 6.24 implies that for an arbitrary sentence $\phi \in \mathcal{D}^2[\tau]$ there is a sentence $\phi' := \phi^*(\top/R) \in \mathcal{ESO}[\tau]$ such that for all $\mathfrak{A}$ it holds that

$$\begin{aligned} \mathfrak{A} \models \phi \quad &\text{iff} \quad \mathfrak{A} \models_{\{\emptyset\}} \phi \\ &\text{iff} \quad (\mathfrak{A}, \{\emptyset\}) \models \phi^* \\ &\text{iff} \quad \mathfrak{A} \models \phi'. \end{aligned} \tag{6.14}$$

Note that if $\phi \in \mathcal{D}^2$ does not contain any dependence atoms, i. e. $\phi \in \mathcal{FO}^2$, then the sentence ϕ^* is of the form

$$\exists R_1 \ldots \exists R_k(\forall x \forall y \psi \wedge \bigwedge_i \forall x \exists y \theta_i)$$

and the first-order part of this is in *Scott normal form* (cf. [Sco62]). So, in Theorem 6.24 we essentially translate formulas of $\mathcal{D}^2$ into Scott normal form.

Theorem 6.24 now implies the main theorem of this section.

Theorem 6.25. *$\mathcal{D}^2$-SAT and $\mathcal{D}^2$-FINSAT are* NEXP*-complete.*

PROOF. Let $\phi \in \mathcal{D}^2[\tau]$ be a sentence. Then, by Eq. (6.14), ϕ is (finitely) satisfiable if and only if ϕ' is. Now ϕ' is of the form

$$\exists R_1 \ldots \exists R_k \psi,$$

Logic	Complexity of SAT / FINSAT	Reference
$\mathcal{FO}, \mathcal{FO}^3$	Π^0_1 / Σ^0_1	[Chu36, Tur36]
$\mathcal{ESO}, \mathcal{D}, \mathcal{IF}$	Π^0_1 / Σ^0_1	Remark 2.19, [Chu36, Tur36]
$\mathcal{FO}^2$	NEXP	[GKV97]
$\mathcal{FOC}^2$	NEXP	[PH05]
$\mathcal{D}^2$	NEXP	Theorem 6.25
$\mathcal{IF}^2$	Π^0_1 / Σ^0_1	Theorems 6.19 and 6.23

Table 6.1: Complexity for extensions / restrictions of first-order logic. The results are completeness results for the full relational vocabulary.

where $\psi \in \mathcal{FOC}^2$. Clearly, ϕ' is (finitely) satisfiable iff ψ is (finitely) satisfiable as a $\mathcal{FOC}^2[\tau \cup \{R_1, \ldots, R_k\}]$ sentence. Now since the mapping $\phi \mapsto \phi'$ is computable in polynomial time and (finite) satisfiability of ψ can be checked in NEXP [PH05], we get that $\mathcal{D}^2$-SAT, $\mathcal{D}^2$-FINSAT $\in$ NEXP.

On the other hand, since $\mathcal{FO}^2$ is a sublogic of $\mathcal{D}^2$ and $\mathcal{FO}^2$-SAT, $\mathcal{FO}^2$-FINSAT are NEXP-hard [GKV97], it follows that $\mathcal{D}^2$-SAT and $\mathcal{D}^2$-FINSAT are NEXP-hard as well. ∎

6.4 CONCLUSION

We have studied the complexity of the two-variable fragments of dependence logic and independence-friendly logic. We have shown that both the satisfiablity and finite satisfiability problems for $\mathcal{D}^2$ are decidable and, in fact, even NEXP-complete. Also we have proved that both problems are undecidable for $\mathcal{IF}^2$; the satisfiability and finite satisfiabity problems for $\mathcal{IF}^2$ are Π^0_1-complete and Σ^0_1-complete, respectively. Table 6.1 gives an overview of our complexity results as well as previously-known results.

While the full logics $\mathcal{D}$ and $\mathcal{IF}$ are expressively equivalent over sentences, we have shown that the finite variable variants $\mathcal{D}^2$ and $\mathcal{IF}^2$ are not, the latter being more expressive (Theorem 6.3 and Proposition 6.5). This was obtained as a by-product of the deeper result concerning the decidability barrier between these two logics.

An interesting open question concerns the complexity of the *validity* (or *tautology*) problem for $\mathcal{D}^2$ and $\mathcal{IF}^2$, i. e. the problem in which a formula over a vocabulary τ is given and the problem is to decide whether *all* τ-structures satisfy the formula. For plain first-order logic the complexity of the validity problem is the dual of the complexity of the satisfiability problem because for all $\phi \in \mathcal{FO}$ it holds that

$$\phi \in \mathcal{FO}\text{-}\textsc{Sat} \quad \text{iff} \quad \neg\phi \notin \mathcal{FO}\text{-}\textsc{Taut}.$$

This, however, does not hold for $\mathcal{D}$ or $\mathcal{IF}$ since for these logics the law of excluded middle does not hold (cf. Proposition 3.4). Hence, it is not even clear whether $\mathcal{D}^2$-TAUT is decidable.
